Preface

This web-book is derived from my lecture slides for the Spring 2023 session of Epidemiology 204: "Quantitative Epidemiology III: Statistical Models", at UC Davis.

I have drawn these materials from many sources, including but not limited to:

- https://www.taylorfrancis.com/books/mono/10.1201/9781315182780/introduction-generalized-linear-models-adrian-barnett-annette-dobson
- https://dmrocke.ucdavis.edu/Class/EPI204-Spring-2021/EPI204-Spring-2021.html
- https://link.springer.com/book/10.1007/978-1-4614-1353-0

License

This book is licensed to you under [Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 International License][http://creativecommons.org/licenses/by-nc-nd/4.0/].

The code samples in this book are licensed under [Creative Commons CC0 1.0 Universal (CC0 1.0)][https://creativecommons.org/publicdomain/zero/1.0/], i.e. public domain.

0.1 Introduction

Configuring R

Functions from these packages will be used throughout this document:

```
library(ggeasy) # help with graphics
library(plotly) # interactive graphics
library(dplyr) # manipulate data
library(tidyr) # Tools to help to create tidy data
library(haven) # import Stata files
library(pander) # format tables for markdown
library(knitr) # format R output for markdown
library(kableExtra) # more markdown formatting
library(parameters) # format model output tables for markdown
library(reactable) # interactive tables
library(dobson) # datasets from Dobson and Barnett 2018
library(conflicted) # check for conflicting function definitions
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
knitr::opts_chunk$set(warning = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
options('digits' = 4)
conflicts_prefer(dplyr::filter)
conflicts_prefer(ggplot2::autoplot)
```

0.2 Introduction to Epi 204

Welcome to Epidemiology 204: Quantitative Epidemiology III (Statistical Models).

In this course, we will start where Epi 203 left off: with linear regression models.

If you haven't taken Epi 203 or a similar introduction to mathematical statistical inference, please talk to me after class.

0.2.1 What you should know

Epi 202: probability models for different data types

- binomial
- Poisson
- Gaussian
- exponential

Epi 203: inference for one or several homogenous populations

- the maximum likelihood inference framework:
 - likelihood functions
 - log-likelihood functions
 - score functions
 - estimating equations
 - information matrices
 - point estimates
 - standard errors
 - confidence intervals
 - hypothesis tests
 - p-values
- Hypothesis tests for one, two, and >2 groups:
 - t-tests/ANOVA for Gaussian models
 - chi-square tests for binomial and Poisson models
- Some linear regression

Stat 108: linear regression models

- building models for Gaussian outcomes
 - multiple predictors
 - interactions
- regression diagnostics
- fundamentals of R programming; e.g.:
 - R
 for Data Science (Wickham, Cetinkaya-Rundel, Grolemund
 $2023)^{1}$
 - Introductory Statistics with R (Dalgaard 2008)²
- RMarkdown or Quarto for formatting homework
- LaTeX for writing math in RMarkdown/Quarto

0.2.2 What we will cover in this course

- Linear (Gaussian) regression models (review and more details)
- Regression models for non-Gaussian outcomes
 - binary
 - count
 - time to event
- Statistical analysis using R

0.3 Regression models

Why do we need them?

- continuous predictors
- not enough data to analyze some subgroups individually

¹https://r4ds.hadley.nz/

 $^{{}^2} https://link.springer.com/book/10.1007/978-0-387-79054-1$

0.3.1 Example: Adelie penguins

```
library(ggplot2)
library(plotly)
library(dplyr)
ggpenguins <-
   palmerpenguins::penguins |>
   dplyr::filter(species == "Adelie") |>
   ggplot(
    aes(x = bill_length_mm , y = body_mass_g)) +
   geom_point() +
   xlab("Bill length (mm)") +
   ylab("Body mass (g)")
ggpenguins |> print()
```

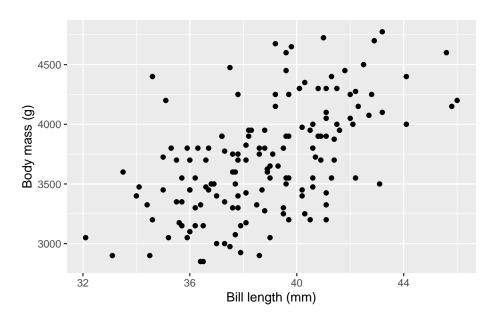

Figure 1: Palmer penguins

0.3.2 Linear regression

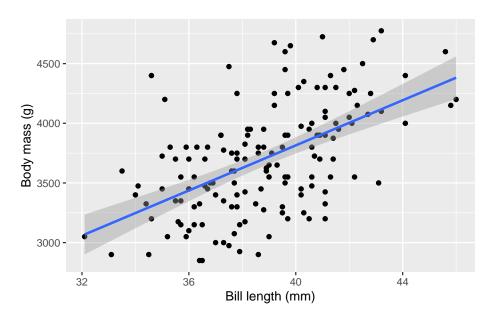

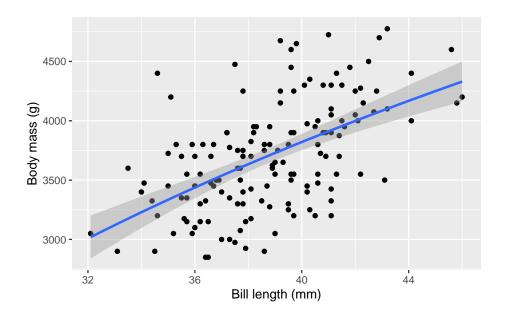

Figure 2: Palmer penguins with linear regression fit

0.3.3 Curved regression lines

```
ggpenguins2 = ggpenguins +
   stat_smooth(
   method = "lm",
   formula = y ~ log(x),
   geom = "smooth") +
   xlab("Bill length (mm)") +
   ylab("Body mass (g)")

ggpenguins2 |> print()
```

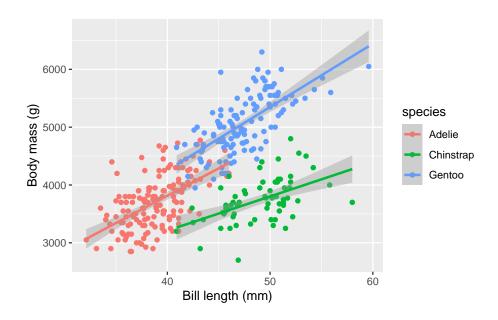

0.3.4 Multiple regression

```
ggpenguins =
  palmerpenguins::penguins |>
  ggplot(
    aes(x = bill_length_mm ,
        y = body_mass_g,
        color = species
    )
  ) +
  geom_point() +
  stat_smooth(
  method = "lm",
  formula = y ~ x,
```

```
geom = "smooth") +
xlab("Bill length (mm)") +
ylab("Body mass (g)")

ggpenguins |> print()
```

0.3.5 Modeling non-Gaussian outcomes

```
library(glmx)
data(BeetleMortality)
beetles = BeetleMortality |>
  mutate(
    pct = died/n,
```

```
survived = n - died
)

plot1 =
  beetles |>
  ggplot(aes(x = dose, y = pct)) +
  geom_point(aes(size = n)) +
  xlab("Dose (log mg/L)") +
  ylab("Mortality rate (%)") +
  scale_y_continuous(labels = scales::percent) +
  # xlab(bquote(log[10]), bquote(CS[2])) +
  scale_size(range = c(1,2))
print(plot1)
```

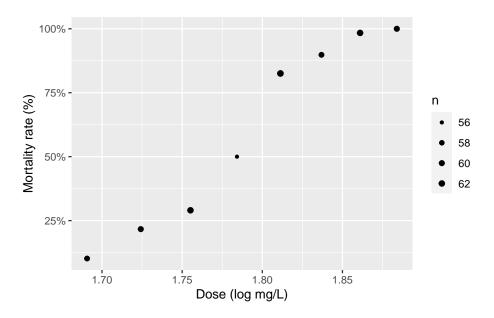

Figure 3: Mortality rates of adult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.3.6 Why don't we use linear regression?

```
beetles_long =
  beetles |>
  reframe(.by = everything(),
      outcome = c(
      rep(1, times = died),
      rep(0, times = survived))
)

lm1 =
```

```
beetles_long |>
lm(
   formula = outcome ~ dose,
   data = _)

range1 = range(beetles$dose) + c(-.2, .2)

f.linear = function(x) predict(lm1, newdata = data.frame(dose = x))

plot2 =
   plot1 +
   geom_function(fun = f.linear, aes(col = "Straight line")) +
   labs(colour="Model", size = "")

print(plot2)
```

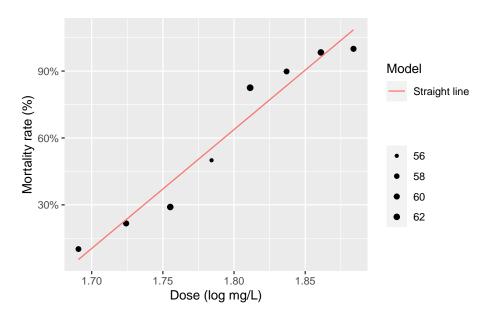

Figure 4: Mortality rates of a dult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.3.7 Zoom out

```
print(plot2 + expand_limits(x = c(1.6, 2)))
```

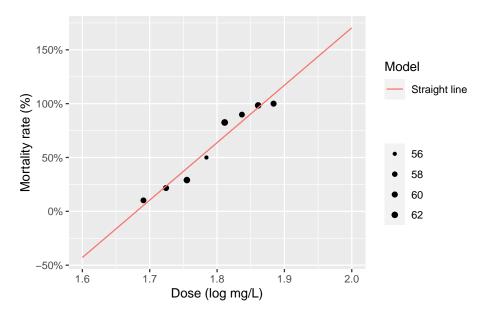

Figure 5: Mortality rates of adult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.3.8 log transformation of dose?

```
lm2 =
  beetles_long |>
  lm(formula = outcome ~ log(dose), data = _)

f.linearlog = function(x) predict(lm2, newdata = data.frame(dose = x))

plot3 = plot2 +
  expand_limits(x = c(1.6, 2)) +
  geom_function(fun = f.linearlog, aes(col = "Log-transform dose"))
```

```
print(plot3 + expand_limits(x = c(1.6, 2)))
```

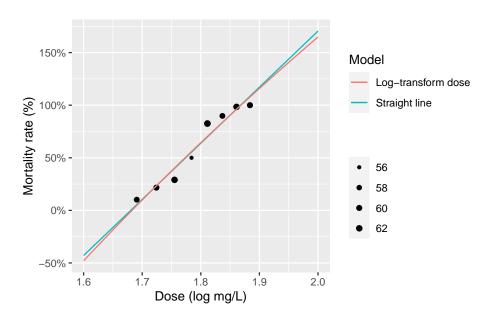

Figure 6: Mortality rates of adult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.3.9 Logistic regression

```
glm1 = beetles |>
   glm(formula = cbind(died, survived) ~ dose, family = "binomial")

f = function(x) predict(glm1, newdata = data.frame(dose = x), type = "response")

plot4 = plot3 + geom_function(fun = f, aes(col = "Logistic regression"))
```

print(plot4)

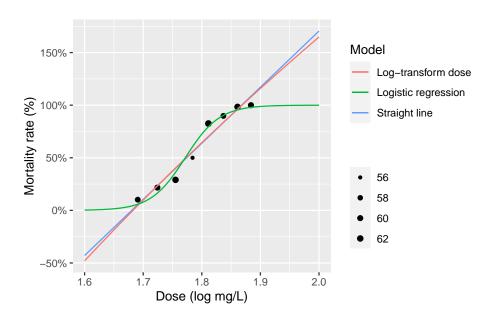

Figure 7: Mortality rates of adult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.3.10 Three parts to regression models

- What distribution does the outcome have for a specific subpopulation defined by covariates? (outcome model)
- How does the combination of covariates relate to the mean? (link function)
- How do the covariates combine? (linear predictor, interactions)

This section is primarily adapted starting from the textbook "An Introduction to Generalized Linear Models" (4th edition, 2018) by Annette J. Dobson and Adrian G. Barnett:

https://www.routledge.com/An-Introduction-to-Generalized-Linear-Models/Dobson-Barnett/p/book/9781138741515

The type of predictive model one uses depends on several issues; one is the type of response.

- Measured values such as quantity of a protein, age, weight usually can be handled in an ordinary linear regression model, possibly after a log transformation.
- Patient survival, which may be censored, calls for a different method (survival analysis, Cox regression).
- If the response is binary, then can we use logistic regression models
- If the response is a count, we can use Poisson regression
- If the count has a higher variance than is consistent with the Poisson, we can use a negative binomial or over-dispersed Poisson
- Other forms of response can generate other types of generalized linear models

We need a linear predictor of the same form as in linear regression x. In theory, such a linear predictor can generate any type of number as a prediction, positive, negative, or zero

We choose a suitable distribution for the type of data we are predicting (normal for any number, gamma for positive numbers, binomial for binary responses, Poisson for counts)

We create a link function which maps the mean of the distribution onto the set of all possible linear prediction results, which is the whole real line $(-\infty, \infty)$. The inverse of the link function takes the linear predictor to the actual prediction.

- Ordinary linear regression has identity link (no transformation by the link function) and uses the normal distribution
- If one is predicting an inherently positive quantity, one may want to use the log link since ex is always positive.
- An alternative to using a generalized linear model with a log link, is to transform the data using the log. This is a device that works well with measurement data and may be usable in other cases, but it cannot be used for 0/1 data or for count data that may be 0.

Table 1: R glm() Families

Family	Links
gaussian	identity, log, inverse
binomial	logit, probit, cauchit, log, cloglog
gamma	inverse , identity, log
inverse.gaussian	1/mu^2, inverse, identity, log
Poisson	log, identity, sqrt
quasi	identity, logit, probit, cloglog,
_	inverse, log, 1/mu^2 and sqrt
quasibinomial	logit, probit, identity, cloglog,
_	inverse, log, 1/mu ² and sqrt
quasipoisson	log, identity, logit, probit, cloglog,
	inverse, $1/\text{mu}^2$ and sqrt

	<u> </u>		Link	Inverse Link
Name	Domain	Range	Function	Function
identity	$(-\infty, \infty)$	$(-\infty,\infty)$	$\eta = \mu$	$\mu = \eta$
log	$(0,\infty)$	$(-\infty, \infty)$	$\eta = \log \mu$	$\mu = \exp \eta$
inverse	$(0,\infty)$	$(0,\infty)$	$\eta = 1/\mu$	$\mu = 1/\eta$
logit	(0,1)	$(-\infty, \infty)$	$\eta =$	$\mu =$
			$\log \mu/(1-\mu)$	μ) $exp\eta/(1 +$
				$exp\eta)$
probit	(0, 1)	$(-\infty, \infty)$	$\eta = \Phi^- 1 \mu$	$\mu = \Phi(\eta)$
cloglog	(0,1)	$(-\infty, \infty)$	$\eta =$	$\mu =$
			$\log - \log 1$	$-\mu 1 - \exp - \exp$
1/mu^2	$(0,\infty)$	$(0,\infty)$	$\eta = 1/\mu^2$	$\mu = 1/\sqrt(\eta)$
sqrt	$(0,\infty)$	$(0,\infty)$	$\eta = \sqrt{\mu}$	$\mu = \eta^2$

Table 2: R glm() Link Functions; $\eta = X\beta = g(\mu)$

0.4 Linear (Gaussian) Models

Note

This content is adapted from Dobson & Barnett, An Introduction to Generalized Linear Models, 4th edition, Chapters 2-6]

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
library(ggeasy) # help with graphics
library(dplyr) # manipulate data
library(haven) # import Stata files
```

```
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
```

0.5 Understanding Gaussian Linear Regression Models

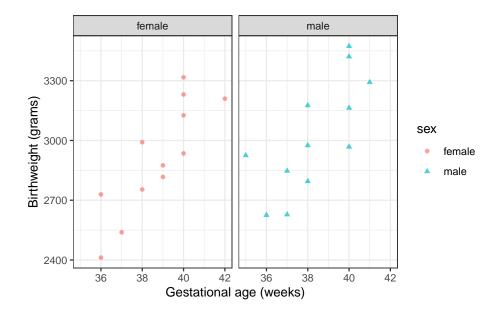

0.5.1 Motivating example: birthweights and gestational age

Suppose we want to learn about the distributions of birthweights for (human) babies born at different gestational ages and with different chromosomal sexes (Dobson and Barnett, Example 2.2.2):

```
data("birthweight", package = "dobson")

bw =
   birthweight |>
   pivot_longer(
    cols = everything(),
    names_to = c("sex", ".value"),
    names_sep = "s "
   ) |>
   mutate(
    sex = ifelse(sex == "boy", "male", "female"),
    male = (sex == "male") |> as.integer()) |>
   rename(age = `gestational age`)
```

```
plot1 = bw |>
  ggplot(aes(
    x = age,
    y = weight,
    linetype = sex,
    shape = sex,
    col = sex)) +
  theme_bw() +
  xlab("Gestational age (weeks)") +
  ylab("Birthweight (grams)") +
  # expand_limits(y = 0, x = 0) +
  geom_point(alpha = .7)
```

0.5.2 Parallel lines regression

We don't have enough data to model the distribution of birth weight separately for each combination of gestational age and sex, so let's instead consider a (relatively) simple model for how that distribution varies with gestational age and sex.

0.5.2.1 Notation

Let:

- Y represent birthweight (measured in grams)
- X_1 represent chromosomal sex:
 - $\begin{array}{l} -\ X_1 = 0 \ \mathrm{if\ female\ (XX)} \\ -\ X_1 = 1 \ \mathrm{if\ male\ (XY)} \end{array}$
- X_2 represent gestational age at birth (measured in weeks).

Note

Female is the **reference level** for the categorical variable X_1 (chromosomal sex). The choice of a reference level is arbitrary and does not limit what we can do with the resulting model; it only makes it more computationally convenient to make inferences about comparisons involving that reference group.

Now, consider the following model:

$$Y \sim N(\mu(X_1, X_2), \sigma^2)$$

$$\mu(X_1,X_2) \stackrel{\mathrm{def}}{=} E[Y|X_1,X_2] = \beta_0 + \beta_1 X_1 + \beta_2 X_2$$

0.5.2.2 Implementing the Model in R

Here's how we can implement this model in R:

```
bw_lm1 = lm(
  formula = weight ~ sex + age,
  data = bw)

bw_lm1 |>
  parameters(show_sigma = TRUE) |>
  print_md()
```

Parameter	Coefficient	SE	95% CI	t(21)	p
(Intercept)	-1773.32	794.59	(-3425.75, -120.89)	-2.23	0.037
sex (male)	163.04	72.81	(11.63, 314.45)	2.24	0.036
age	120.89	20.46	(78.34, 163.45)	5.91	< .001

Here's how this model looks, superimposed on the data:

```
bw =
  bw |>
  mutate(`E[Y|X=x]` = fitted(bw_lm1)) |>
  arrange(sex, age)

plot2 =
  plot1 %+% bw +
  geom_line(aes(y = `E[Y|X=x]`))

print(plot2)
```

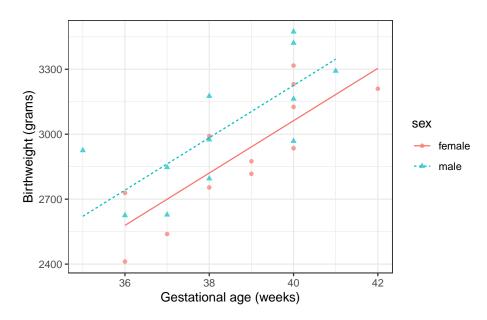

Figure 8: Parallel-slopes model of birthweight

0.5.2.3 Model assumptions and predictions

To learn what this model is assuming, let's plug in a few values.

According to this model, what's the mean birthweight for a female born at 36 weeks?

```
pred_female = coef(bw_lm1)["(Intercept)"] + coef(bw_lm1)["age"]*36

# print(pred_female)
## built-in prediction:
# predict(bw_lm1, newdata = tibble(sex = "female", age = 36))
```

$$E[Y|X_1 = 0, X_2 = 36] = \beta_0 + \beta_1 \cdot 0 + \beta_2 \cdot 36 = 2578.8739$$

What's the mean birthweight for a male born at 36 weeks?

```
pred_male =
   coef(bw_lm1)["(Intercept)"] +
   coef(bw_lm1)["sexmale"] +
   coef(bw_lm1)["age"]*36
```

$$E[Y|X_1 = 1, X_2 = 36] = \beta_0 + \beta_1 \cdot 1 + \beta_2 \cdot 36 = 2741.9132$$

What's the difference in mean birthweights between males born at 36 weeks and females born at 36 weeks?

$$\begin{split} E[Y|X_1 = 1, X_2 = 36] - E[Y|X_1 = 0, X_2 = 36] \\ &= 2741.9132 - 2578.8739 \\ &= 163.0393 \end{split}$$

Shortcut:

$$\begin{split} E[Y|X_1 = 1, X_2 = 36] - E[Y|X_1 = 0, X_2 = 36] \\ &= (\beta_0 + \beta_1 \cdot 1 + \beta_2 \cdot 36) - (\beta_0 + \beta_1 \cdot 0 + \beta_2 \cdot 36) \\ &= \beta_1 \\ &= 163.0393 \end{split}$$

Note that age doesn't show up in this difference: in other words, according to this model, the difference between females and males with the same gestational age is the same for every age.

That's an assumption of the model; it's built-in to the parametric structure, even before we plug in the estimated values of those parameters.

That's why the lines are parallel.

0.5.3 Interactions

What if we don't like that parallel lines assumption?

Then we need to allow an "interaction" between age and sex:

$$E[Y|X_1,X_2]=\beta_0+\beta_1X_1+\beta_2X_2+\beta_3(X_1\cdot X_2)$$
 bw_lm2 = lm(weight ~ sex + age + sex:age, data = bw)

Here are the estimated parameters (β s):

```
bw_lm2 |>
  parameters() |>
  print_md()
```

Parameter	Coefficient	SE	95% CI	t(20)	p
(Intercept)	-2141.67	1163.60	(-4568.90, 285.56)	-1.84	0.081
sex (male)	872.99	1611.33	(-2488.18, 4234.17)	0.54	0.594
age	130.40	30.00	(67.82, 192.98)	4.35	< .001
$\begin{array}{l} \text{sex (male)} \times \\ \text{age} \end{array}$	-18.42	41.76	(-105.52, 68.68)	-0.44	0.664

Here's another way we could rewrite this model (by collecting terms involving X_2):

$$E[Y|X_1, X_2] = \beta_0 + \beta_1 X_1 + (\beta_2 + \beta_3 X_1) X_2$$

Note

If you want to understand a coefficient in a model with interactions, collect terms for the corresponding variable, and you will see what other variables are interacting with the variable you are interested in.

In this case, the coefficient X_2 is interacting with X_1 . So the slope of Y with respect to X_2 depends on the value of X_2 .

There is no longer a slope; we can't talk about "the slope of birthweight with respect to age". We can only talk about "the slope of birthweight with respect to age among males" and "the slope of birthweight with respect to age among females".

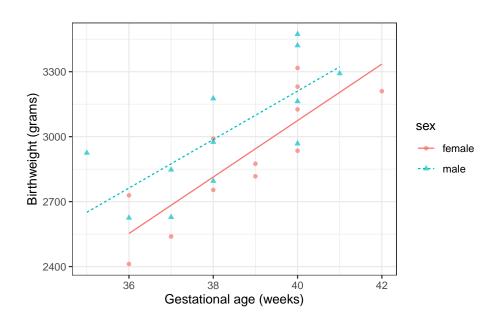

Then: that coefficient is the difference in means per unit change in its corresponding coefficient, when the other collected variables are set to 0.

Here's how this model looks, superimposed on the data:

```
bw =
  bw |>
  mutate(
    predlm2 = predict(bw_lm2)
  ) |>
  arrange(sex, age)

plot1_interact =
  plot1 %+% bw +
  geom_line(aes(y = predlm2))
```

print(plot1_interact)

Now we can see that the lines aren't parallel.

To learn what this model is assuming, let's plug in a few values.

According to this model, what's the mean birthweight for a female born at 36 weeks?

$$E[Y|X_1=0,X_2=36] = \beta_0 + \beta_1 \cdot 0 + \beta_2 \cdot 36 + \beta_3 \cdot (0*36) = 2552.7333$$

What's the mean birthweight for a male born at 36 weeks?

```
pred_male =
  coef(bw_lm2)["(Intercept)"] +
  coef(bw_lm2)["sexmale"] +
  coef(bw_lm2)["age"]*36 +
  coef(bw_lm2)["sexmale:age"] * 36
```

$$E[Y|X_1=0,X_2=36] = \beta_0 + \beta_1 \cdot 1 + \beta_2 \cdot 36 + \beta_3 \cdot 1 \cdot 36 = 2762.7069$$

What's the difference in mean birthweights between males born at 36 weeks and females born at 36 weeks?

$$\begin{split} E[Y|X_1 = 1, X_2 = 36] - E[Y|X_1 = 0, X_2 = 36] \\ &= (\beta_0 + \beta_1 \cdot 1 + \beta_2 \cdot 36 + \beta_3 \cdot 1 \cdot 36) \\ &- (\beta_0 + \beta_1 \cdot 0 + \beta_2 \cdot 36 + \beta_3 \cdot 0 \cdot 36) \\ &= \beta_2 + \beta_3 \cdot 36 \\ &= 209.9736 \end{split}$$

Note that age now does show up in the difference: in other words, according to this model, the difference in mean birthweights between females and males with the same gestational age can vary by gestational age.

That's how the lines in the graph ended up non-parallel.

0.5.4 Stratified regression

We could re-write the interaction model as a stratified model, with a slope and intercept for each sex:

```
bw_lm_strat =
  bw |>
```

```
lm(
    formula = weight ~ sex + sex:age - 1,
    data = _)

bw_lm_strat |>
    parameters() |>
    print_md()
```

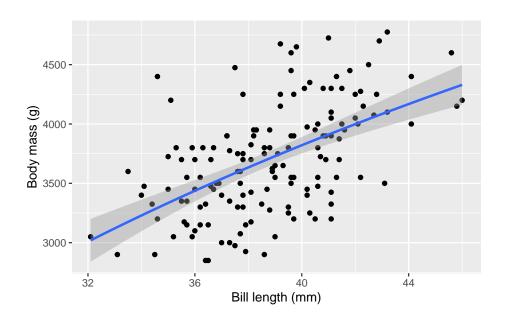

Parameter	Coefficient	SE	95% CI	t(20)	р
sex (female)	-2141.67	1163.60	(-4568.90, 285.56)	-1.84	0.081
sex (male)	-1268.67	1114.64	(-3593.77, 1056.42)	-1.14	0.268
$\begin{array}{l} \text{sex (female)} \times \\ \text{age} \end{array}$	130.40	30.00	(67.82, 192.98)	4.35	< .001
$sex (male) \times age$	111.98	29.05	(51.39, 172.57)	3.86	< .001

0.5.5 Curved-line regression

If we transform some of our covariates (Xs) and plot the resulting model on the original covariate scale, we end up with curved regression lines:

```
bw_lm3 = lm(weight ~ sex:log(age) - 1, data = bw)
library(palmerpenguins)

ggpenguins <-
palmerpenguins::penguins |>
dplyr::filter(species == "Adelie") |>
ggplot(
```

0.6 Estimating Linear Models via Maximum Likelihood

0.6.1 Review of one-sample inference

Previously, we learned how to fit outcome-only models of the form $p(X=x|\theta)$ to iid data $\mathbf{x}=(x_1,...,x_n)$ using maximum likelihood estimation:

$$\begin{split} \mathcal{L}(\mathbf{x}|\theta) &= p(X_1 = x_1, ..., X_n = x_n|\theta) = \prod_{i=1}^n p(X = x_i|\theta) \\ & \qquad \ell(x|\theta) = \log \left\{ \mathcal{L}(x|\theta) \right\} \end{split}$$

$$\hat{\theta}_{ML} = \arg\max_{\theta} \ell(x|\theta)$$

We learned how to quantify our uncertainty about these maximum likelihood estimates; with sufficient sample size, $\hat{\theta}_{ML}$ has the approximate distribution:

$$\hat{\theta}_{ML}\dot{\sim}N(\theta,\mathcal{I}(\theta)^{-1})$$

For models in the "exponential family" of distributions, which includes the Gaussian, Poisson, Bernoulli, Binomial, Exponential, and Gamma distributions, $\mathcal{I}(\theta) = -E[l''(X|\theta)]$, so we estimated $\mathcal{I}(\theta)$ using either $\mathcal{I}(\theta)|_{\theta=\hat{\theta}_{ML}}$ or $l''(\mathbf{x}|\theta)|_{\theta=\hat{\theta}_{ML}}$.

Then an asymptotic approximation of a 95% confidence interval for θ_k is

$$\hat{\theta}_{ML} \pm z_{0.975} \times \left[\left(\hat{\mathcal{I}}(\hat{\theta}_{ML}) \right)^{-1} \right]_{kk}$$

where z_{β} the β quantile of the standard Gaussian distribution.

0.6.2 MLEs for Linear Regression

Let's use maximum likelihood again:

$$\mathcal{L}(\mathbf{y}|\mathbf{x},\boldsymbol{\beta},\sigma^2) = \prod_{i=1}^n (2\pi\sigma^2)^{-1/2} \mathrm{exp} \left\{ -\frac{1}{2\sigma^2} (y_i - x_i'\boldsymbol{\beta})^2 \right\}$$

$$\ell(\mathbf{y}|\mathbf{x},\beta,\sigma^2) \propto -\frac{n}{2} \log\left\{\sigma^2\right\} - \frac{1}{2\sigma^2} \sum_{i=1}^n (y_i - x_i'\beta)^2$$

$$\ell'(\mathbf{y}|\mathbf{x},\beta,\sigma^2) \propto -\frac{n}{2} \log\left\{\sigma^2\right\} - \frac{1}{2\sigma^2} \frac{d}{d\beta} \left(\sum_{i=1}^n (y_i - x_i'\beta)^2 \right)$$

A few tools from linear algebra will make this analysis go easier (see Fieller³, Section 7.2 for details).

$$f_{\beta}(\mathbf{x}) = (f_{\beta}(x_1), f_{\beta}(x_2), ..., f_{\beta}(x_n))^{\top}$$

Let **x** and β be vectors of length p, or in other words, matrices of length $p \times 1$:

$$x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_p \end{bmatrix} \beta = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{bmatrix}$$

Then

$$x'\equiv x^\top \equiv [x_1,x_2,...,x_p]$$

 $^{^3} https://www.taylorfrancis.com/books/mono/10.1201/9781315370200/basics-matrix-algebra-statistics-nick-fieller$

and

$$x'\beta = [x_1, x_2, ..., x_p] \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{bmatrix} = x_1\beta_1 + x_2\beta_2 + ... + x_p\beta_p$$

If $f(\beta)$ is a function that takes β as input and outputs a scalar, such as $f(\beta) = x'\beta$, then:

$$\frac{d}{d\beta}f(\beta) = \begin{bmatrix} \frac{d}{d\beta_1}f(\beta) \\ \frac{d}{d\beta_2}f(\beta) \\ \vdots \\ \frac{d}{d\beta_p}f(\beta) \end{bmatrix}$$

In particular, if $f(\beta) = x'\beta$, then:

$$\frac{d}{d\beta}x'\beta = \begin{bmatrix} \frac{d}{d\beta_1}(x_1\beta_1 + x_2\beta_2 + \dots + x_p\beta_p) \\ \frac{d}{d\beta_2}(x_1\beta_1 + x_2\beta_2 + \dots + x_p\beta_p) \\ \vdots \\ \frac{d}{d\beta_p}(x_1\beta_1 + x_2\beta_2 + \dots + x_p\beta_p) \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_p \end{bmatrix} = \mathbf{x}$$

In general:

$$\frac{d}{d\beta}x'\beta = x$$

This looks a lot like non-vector calculus, except that you have to transpose the coefficient.

Similarly,

$$\frac{d}{d\beta}\beta'\beta = 2\beta$$

This is like taking the derivative of x^2 .

And finally, if S is a $p \times p$ matrix, then:

$$\frac{d}{d\beta}\beta'S\beta = 2S\beta$$

Again, this is like taking the derivative of cx^2 with respect to c in non-vector calculus.

Thus:

$$\sum_{i=1}^n (y_i - f_{\beta}(x_i))^2 = (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta)$$

$$(\mathbf{y} - X\beta)' = (\mathbf{y}' - (X\beta)') = (\mathbf{y}' - \beta'X')$$

So

$$\begin{split} (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) &= (\mathbf{y}' - \beta'X')(\mathbf{y} - X\beta) \\ &= y'y - \beta'X'y - y'X\beta + \beta'X'X\beta \\ &= y'y - 2y'X\beta + \beta'X'X\beta \end{split}$$

So

$$\begin{split} \frac{d}{d\beta} \left(\sum_{i=1}^n (y_i - x_i'\beta)^2 \right) &= \frac{d}{d\beta} (\mathbf{y} - X\beta)' (\mathbf{y} - X\beta) \\ &= \frac{d}{d\beta} (y'y - 2y'X\beta + \beta'X'X\beta) \\ &= (-2X'y + 2X'X\beta) \end{split}$$

So if $\ell(\beta, \sigma^2) = 0$, then

$$0 = (-2X'y + 2X'X\beta)$$

$$2X'y = 2X'X\beta$$

$$X'y = X'X\beta$$

$$(X'X)^{-1}X'y = \beta$$

The second derivative matrix $\ell''_{\beta,\beta'}(\beta,\sigma^2;\mathbf{X},\mathbf{y})$ is negative definite at $\beta=(X'X)^{-1}X'y$, so $\hat{\beta}_{ML}=(X'X)^{-1}X'y$ is the MLE for β .

Similarly (not shown):

$$\hat{\sigma}_{ML}^2 = \frac{1}{n} (Y - X \hat{\beta})' (Y - X \hat{\beta})$$

And

$$\begin{split} \mathcal{I}_{\beta} &= E[-\ell_{\beta,\beta'}'(Y|X,\beta,\sigma^2)] \\ &= \frac{1}{\sigma^2} X' X \end{split}$$

So:

$$Var(\hat{\beta})\approx (\mathcal{I}_{\beta})^{-1}=\sigma^2(X'X)^{-1}$$

and

$$\hat{eta} \dot{\sim} N(eta, \mathcal{I}_{eta}^{-1})$$

These are all results you have hopefully seen before, and in the Gaussian linear regression case they are exact, not just approximate.

In our model 2 above, this matrix is:

	(Intercept)	sexmale	age	sexmale:age
(Intercept)	1353968	-1353968	-34871.0	34871.0
sexmale	-1353968	2596387	34871.0	-67211.0
age	-34871	34871	899.9	-899.9
sexmale:age	34871	-67211	-899.9	1743.5

Note that if we take the square roots of the diagonals, we get the standard errors listed in the model output:

	Estimate	Std. Error	t value	$\Pr(> t)$
(Intercept)	-2,142	1,164	-1.841	0.08057
sexmale	873	1,611	0.5418	0.594

Generalized Linear Models

	Estimate	Std. Error	t value	$\Pr(> t)$
age	130.4	30	4.347	$0.0003127 \\ 0.6639$
sexmale:age	-18.42	41.76	-0.4411	

So we can do confidence intervals, hypothesis tests, and p-values exactly as in the one-variable case we looked at previously.

0.7 Inference about Gaussian Linear Regression Models

Research question: is there really an interaction between sex and age?

$$\begin{split} &H_0: \beta_3 = 0 \\ &H_A: \beta_3 \neq 0 \\ &P(|\hat{\beta}_3| > |-18.4172| \mid H_0) = ? \end{split}$$

0.7.1 Wald tests and CIs

R can give you Wald tests for single coefficients and corresponding CIs:

```
bw_lm2 |>
  parameters(ci_method = "wald") |>
  print_md()
```

Parameter	Coefficient	SE	95% CI	t(20)	p
$\overline{\text{(Intercept)}}$	-2141.67	1163.60	(-4568.90, 285.56)	-1.84	0.081

Parameter	Coefficient	SE	95% CI	t(20)	р
sex (male)	872.99	1611.33	(-2488.18, 4234.17)	0.54	0.594
age	130.40	30.00	(67.82, 192.98)	4.35	< .001
$\frac{\text{sex (male)}}{\text{age}} \times$	-18.42	41.76	(-105.52, 68.68)	-0.44	0.664

0.7.2 One-parameter inference by hand

To understand what's happening, let's replicate these results by hand for the interaction term.

0.7.2.1 P-value

```
beta_hat = coef(summary(bw_lm2))["sexmale:age", "Estimate"]
se_hat = coef(summary(bw_lm2))["sexmale:age", "Std. Error"]
dfresid = bw_lm2$df.residual
t_stat = abs(beta_hat)/se_hat
pval_t = pt(abs(t_stat), df = dfresid, lower = FALSE) * 2
```

$$\begin{split} &P\left(|\hat{\beta}_{3}|>|-18.4172|\Big|H_{0}\right) &=P\left(\left|\frac{\hat{\beta}_{3}}{\hat{SE}(\hat{\beta}_{3})}\right|>\left|\frac{-18.4172}{41.7558}\right|\Big|H_{0}\right)\\ &=P\left(|T_{20}|>0.4411|H_{0}\right)\\ &=0.6639 \end{split}$$

This matches the result in the table above.

0.7.2.2 Confidence interval

```
confint_radius_t = se_hat * qt(p = 0.975, df = dfresid, lower = TRUE) confint_t = beta_hat + c(-1,1) * confint_radius_t print(confint_t)
```

```
[1] -105.52 68.68
```

This also matches.

0.7.3 Gaussian approximations

Here are the asymptotic (Gaussian approximation) equivalents:

0.7.3.1 P-value

```
pval_z = pnorm(abs(t_stat), lower = FALSE) * 2
print(pval_z)
```

[1] 0.6592

0.7.3.2 Confidence interval

```
confint_radius_z = se_hat * qnorm(0.975, lower = TRUE)
confint_z =
  beta_hat + c(-1,1) * confint_radius_z
print(confint_z)
```

```
[1] -100.26 63.42
```

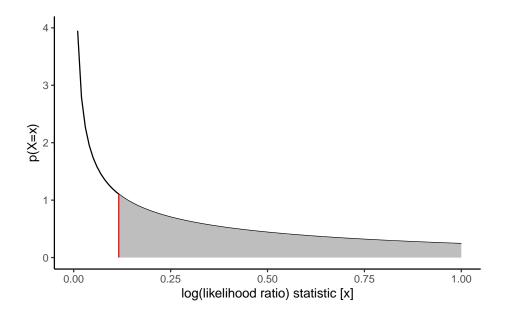

0.7.4 Likelihood ratio statistics

```
logLik(bw_lm2)
'log Lik.' -156.6 (df=5)
  logLik(bw_lm1)
'log Lik.' -156.7 (df=4)
  1LR = (logLik(bw_lm2) - logLik(bw_lm1)) |> as.numeric()
  delta_df = (bw_lm1$df.residual - df.residual(bw_lm2))
  d_lLR = function(x, df = delta_df) dchisq(x, df = df)
  x_max = 1
  chisq_plot =
    ggplot() +
    geom_function(fun = d_lLR) +
    stat_function( fun = d_lLR, xlim = c(lLR, x_max), geom = "area", fill = "gray")
    geom_segment(aes(x = 1LR, xend = 1LR, y = 0, yend = d_1LR(1LR)), col = "red") +
    xlim(0.0001,x_max) +
    ylim(0,4) +
    ylab("p(X=x)") +
    xlab("log(likelihood ratio) statistic [x]") +
    theme classic()
```

```
pchisq(
  q = 2*1LR,
  df = delta_df,
  lower = FALSE)
```

[1] 0.6298

```
chisq_plot |> print()
```

Now we can get the p-value:

```
pchisq(2*1LR, df = delta_df, lower = FALSE)
```

[1] 0.6298

0.7.5

In practice you don't have to do this by hand; there are functions to do it for you:

```
# built in
  library(lmtest)
  lrtest(bw_lm2, bw_lm1)
# A tibble: 2 x 5
  `#Df` LogLik
                  Df Chisq `Pr(>Chisq)`
       <dbl> <dbl>
                      <dbl>
                                   <dbl>
      5 -157.
1
                  NA NA
                                  NA
2
      4 -157.
                  -1 0.232
                                   0.630
```

0.8 Goodness of fit

0.8.1 AIC and BIC

When we use likelihood ratio tests, we are comparing how well different models fit the data.

Likelihood ratio tests require "nested" models: one must be a special case of the other.

If we have non-nested models, we can instead use the Akaike Information Criterion (AIC) or Bayesian Information Criterion (BIC):

- AIC = $-2 * \ell(\hat{\theta}) + 2 * p$
- BIC = $-2 * \ell(\hat{\theta}) + p * \log(n)$

where ℓ is the log-likelihood of the data evaluated using the parameter estimates $\hat{\theta}$, p is the number of estimated parameters in the model (including $\hat{\sigma}^2$), and n is the number of observations.

You can calculate these criteria using the logLik() function, or use the built-in R functions:

0.8.1.1 AIC in R

Large values of AIC and BIC are worse than small values. There are no hypothesis tests or p-values associated with these criteria.

0.8.2 (Residual) Deviance

Let q be the number of distinct covariate combinations in a data set.

```
bw.X.unique =
  bw |>
  count(sex, age)

n_unique.bw = nrow(bw.X.unique)
```

For example, in the birthweight data, there are q = 12 unique patterns:

```
bw.X.unique |>
  pander(
    row.names = rownames(bw.X.unique))
```

	sex	age	n
1	female	36	2
2	female	37	1
3	female	38	2
4	female	39	2
5	female	40	4
6	female	42	1
7	$_{\mathrm{male}}$	35	1
8	male	36	1
9	male	37	2
10	$_{\mathrm{male}}$	38	3
11	$_{\mathrm{male}}$	40	4
12	$_{\mathrm{male}}$	41	1

Note

If a given covariate pattern has more than one observation in a dataset, those observations are called **replicates**.

Then the most complicated model we could fit would have one parameter (a mean) for each of these combinations, plus a variance parameter:

```
lm_max =
  bw |>
  mutate(age = factor(age)) |>
  lm(
    formula = weight ~ sex:age - 1,
    data = _)

lm_max |>
  parameters() |>
  print_md()
```

Parameter	Coefficient	SE	95% CI	t(12)	р
$\overline{\text{sex (male)}} \times$	2925.00	187.92	(2515.55,	15.56	<
age35			3334.45)		.001
$sex (female) \times$	2570.50	132.88	(2280.98,	19.34	<
age36			2860.02)		.001
$sex (male) \times$	2625.00	187.92	(2215.55,	13.97	<
age36			3034.45)		.001
$sex (female) \times$	2539.00	187.92	(2129.55,	13.51	<
age37			2948.45)		.001
$sex (male) \times$	2737.50	132.88	(2447.98,	20.60	<
age37			3027.02)		.001
sex (female) ×	2872.50	132.88	(2582.98,	21.62	<
age38			3162.02)		.001

Generalized Linear Models

Parameter	Coefficient	SE	95% CI	t(12)	p
sex (male) ×	2982.00	108.50	(2745.60,	27.48	<
age38			3218.40)		.001
$sex (female) \times$	2846.00	132.88	(2556.48,	21.42	<
age39			3135.52)		.001
$sex (female) \times$	3152.25	93.96	(2947.52,	33.55	<
age40			3356.98)		.001
$sex (male) \times$	3256.25	93.96	(3051.52,	34.66	<
age40			3460.98)		.001
$sex (male) \times$	3292.00	187.92	(2882.55,	17.52	<
age41			3701.45)		.001
$sex (female) \times$	3210.00	187.92	(2800.55,	17.08	<
age42			3619.45)		.001

We call this model the **full**, **maximal**, or **saturated** model for this dataset.

We can calculate the log-likelihood of this model as usual:

```
logLik(lm_max)
```

'log Lik.' -151.4 (df=13)

We can compare this model to our other models using chi-square tests, as usual:

```
lrtest(lm_max, bw_lm2)
```

The likelihood ratio statistic for this test is

$$\lambda = 2 * (\ell_{\text{full}} - \ell) = 10.3554$$

where:

- $\ell_{\rm max}$ is the log-likelihood of the full model: -151.4016
- ℓ is the log-likelihood of our comparison model (two slopes, two intercepts): -156.5793

This statistic is called the **deviance** or **residual deviance** for our two-slopes and two-intercepts model; it tells us how much the likelihood of that model deviates from the likelihood of the maximal model.

The corresponding p-value tells us whether there we have enough evidence to detect that our two-slopes, two-intercepts model is a worse fit for the data than the maximal model; in other words, it tells us if there's evidence that we missed any important patterns. (Remember, a nonsignificant p-value could mean that we didn't miss anything and a more complicated model is unnecessary, or it could mean we just don't have enough data to tell the difference between these models.)

0.8.3 Null Deviance

Similarly, the *least* complicated model we could fit would have only one mean parameter, an intercept:

$$E[Y|X=x] = \beta_0$$

We can fit this model in R like so:

Parameter	Coefficient	SE	95% CI	t(23)	р
(Intercept)	2967.67	57.58	(2848.56, 3086.77)	51.54	< .001

This model also has a likelihood:

```
logLik(lm0)
```

```
'log Lik.' -169 (df=2)
```

And we can compare it to more complicated models using a likelihood ratio test:

```
lrtest(bw_lm2, lm0)
```

The likelihood ratio statistic for the test comparing the null model to the maximal model is

$$\lambda = 2*(\ell_{\rm full} - \ell_0) = 35.1067$$

where:

- ℓ_0 is the log-likelihood of the null model: -168.955
- $\ell_{\rm full}$ is the log-likelihood of the maximal model: -151.4016

In R, this test is:

```
lrtest(lm_max, lm0)
# A tibble: 2 x 5
  `#Df` LogLik
                  Df Chisq `Pr(>Chisq)`
  <dbl>
         <dbl> <dbl> <dbl>
                                   <dbl>
     13
         -151.
                  NA
                      NA
                               NA
2
      2
        -169.
                 -11
                      35.1
                                0.000238
```

This log-likelihood ratio statistic is called the **null deviance**. It tells us whether we have enough data to detect a difference between the null and full models.

Caution

This definition is a bit different from what I said in class (4/25); then, I said the null deviance was twice the difference in log-likelihood between the model of interest and the null model. The one I have written above is the standard one, and we'll stick to the standard definition going forward.

0.9 Rescaling

0.9.1 Rescale age

Parameter	Coefficient	SE	95% CI	t(20)	p
(Intercept)	2552.73	97.59	(2349.16, 2756.30)	26.16	< .001
sex (male)	209.97	129.75	(-60.68,	1.62	0.121
age - 36wks	130.40	30.00	480.63) (67.82, 192.98)	4.35	<
$sex (male) \times age -$	-18.42	41.76	(-105.52,	-0.44	0.001 0.664
36wks			68.68)		

Compare with what we got without rescaling:

```
parameters(bw_lm2, ci_method = "wald") |> print_md()
```

Parameter	Coefficient	SE	95% CI	t(20)	p
(Intercept)	-2141.67	1163.60	(-4568.90, 285.56)	-1.84	0.081
sex (male)	872.99	1611.33	(-2488.18, 4234.17)	0.54	0.594
age	130.40	30.00	(67.82, 192.98)	4.35	< .001
$\frac{\text{sex (male)} \times}{\text{age}}$	-18.42	41.76	(-105.52, 68.68)	-0.44	0.664

0.10 Prediction

0.10.1 Prediction for linear models

$$\begin{split} \hat{Y} &= \hat{E}[Y|X=x] \\ &= x'\hat{\beta} \\ &= \hat{\beta}_0 \cdot 1 + \hat{\beta}_1 x_1 + \ldots + \hat{\beta}_p x_p \end{split}$$

0.10.2 prediction in R

```

The warning from the last command is: "predictions on current data refer to future responses" (since you already know what happened to the current data, and thus don't need to predict it). You could also supply newdata to get predictions for new combinations of predictors that you didn't see in your original dataset. See ?predict.lm for more.

0.11 Diagnostics

0.11.1 Residuals

0.11.1.1 Definitions of residuals

• Residuals:

$$e_i = y_i - \hat{E}[Y|X = x]$$

• For Gaussian models, e_i can be seen as an estimate of

$$\epsilon_i = Y_i - \mathrm{E}[Y|X = x_i]$$

• Standardized residuals:

$$r_i = \frac{e_i}{\hat{SD}(e_i)}$$

• For Gaussian models:

$$\hat{SD}(e_i) \approx \frac{e_i}{\hat{\sigma}}$$

0.11.1.2 Characteristics of residuals

With enough data and a correct model, the residuals will be approximately Guassian distributed, with variance σ^2 , which we can estimate using $\hat{\sigma}^2$: that is:

$$e_i \stackrel{.}{\sim}_{iid} N(0, \hat{\sigma}^2)$$

Hence, with enough data and a correct model, the standardized residuals will be approximately standard Gaussian; that is,

$$r_i \stackrel{.}{\sim}_{iid} N(0,1)$$

0.11.2 Marginal distributions of residuals

To look for problems with our model, we can check whether the residuals e_i and standardized residuals r_i look like they have the distributions that they are supposed to have, according to the model.

First, we need to compute the residuals. R makes this easy:

0.11.2.1 (non-standardized) residuals in R

```

These are not quite the same, because R is doing something more complicated and precise to get the standard errors. Let's not worry about those details for now; the difference is pretty small in this case:

```
rstandard_compare_plot =
  tibble(
    x = resid(bw_lm2)/sigma(bw_lm2),
    y = rstandard(bw_lm2)) |>
  ggplot(aes(x = x, y = y)) +
  geom_point() +
  theme_bw() +
  coord_equal() +
  xlab("resid(bw_lm2)/sigma(bw_lm2)") +
  ylab("rstandard(bw_lm2)") +
  geom_abline(
    aes(
```

```
intercept = 0,
    slope = 1,
    col = "x=y")) +
    labs(colour="") +
    scale_colour_manual(values="red")

print(rstandard_compare_plot)
```

Let's add these residuals to the tibble of our dataset:

```
bw =
  bw |>
  mutate(
    fitted_lm2 = fitted(bw_lm2),
```

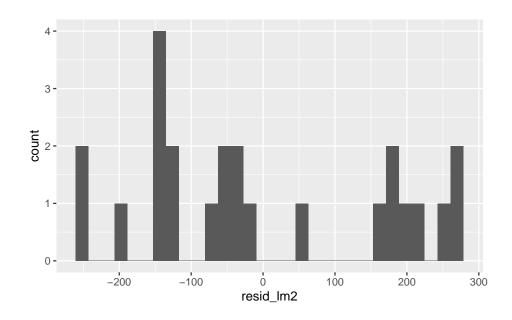

```
resid_lm2 = resid(bw_lm2),
       # resid_lm2 = weight - fitted_lm2,
       std_resid_lm2 = rstandard(bw_lm2),
       # std_resid_lm2 = resid_lm2 / sigma(bw_lm2)
     )
  bw |>
    select(
       sex,
       age,
       weight,
      fitted_lm2,
      resid_lm2,
       std_resid_lm2
    )
# A tibble: 24 x 6
             age weight fitted_lm2 resid_lm2 std_resid_lm2
   sex
   <chr>

                                                       0.306
# i 14 more rows
```

Now let's build histograms:

0.11.2.3 Marginal distribution of (nonstandardized) residuals

```
resid_marginal_hist =
  bw |>
  ggplot(aes(x = resid_lm2)) +
  geom_histogram()

print(resid_marginal_hist)
```

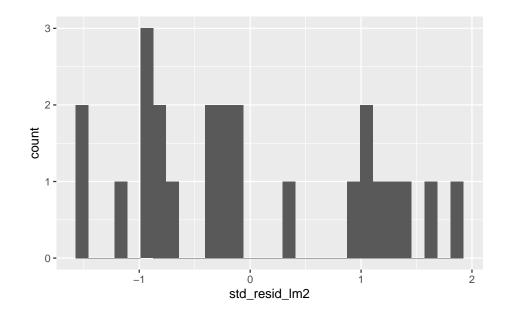

Hard to tell with this small amount of data, but I'm a bit concerned that the histogram doesn't show a bell-curve shape.

Marginal distribution of standardized residuals

```
std_resid_marginal_hist =
  bw |>
  ggplot(aes(x = std_resid_lm2)) +
  geom_histogram()

print(std_resid_marginal_hist)
```

This looks similar, although the scale of the x-axis got narrower, because we divided by $\hat{\sigma}$ (roughly speaking).

Still hard to tell if the distribution is Gaussian.

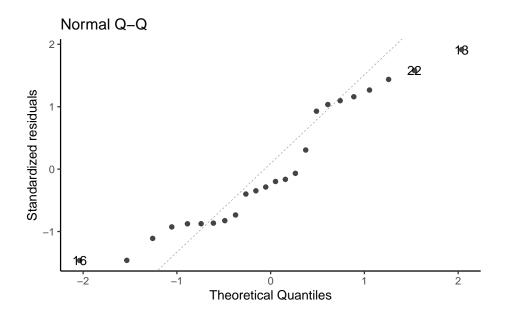

0.11.3 QQ plot of standardized residuals

Another way to assess normality is the QQ plot of the standardized residuals versus normal quantiles:

```
library(ggfortify)
# needed to make ggplot2::autoplot() work for `lm` objects

qqplot_lm2_auto =
   bw_lm2 |>
   autoplot(
    which = 2, # options are 1:6; can do multiple at once
   ncol = 1) +
   theme_classic()

print(qqplot_lm2_auto)
```

If the Gaussian model were correct, these points should follow the dotted line.

Note

Fig 2.4 panel (c) in Dobson is a little different; they didn't specify how they produced it, but other statistical analysis systems do things differently from R.

0.11.3.1 QQ plot - how it's built

Let's construct it by hand:

```
bw = bw |>
 mutate(
    p = (rank(std_resid_lm2) - 1/2)/n(), # "Blom's method"
    expected_quantiles_lm2 = qnorm(p)
qqplot_lm2 =
  bw |>
  ggplot(
    aes(
     x = expected_quantiles_lm2,
     y = std_resid_lm2,
     col = sex,
      shape = sex)
  ) +
  geom_point() +
  theme_classic() +
  theme(legend.position='none') + # removing the plot legend
  ggtitle("Normal Q-Q") +
  xlab("Theoretical Quantiles") +
  ylab("Standardized residuals")
```

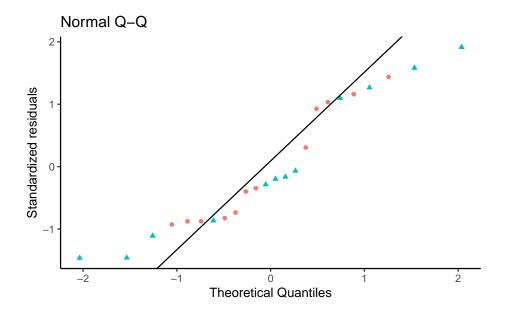

We find the expected line like so:

```
ps <- c(.25, .75)  # reference probabilities
a <- quantile(rstandard(bw_lm2), ps) # empirical quantiles
b <- qnorm(ps)  # theoretical quantiles

qq_slope = diff(a)/diff(b)
qq_intcpt = a[1] - b[1] * qq_slope

qqplot_lm2 =</pre>
```

```
qqplot_lm2 +
  geom_abline(slope = qq_slope, intercept = qq_intcpt)
print(qqplot_lm2)
```

0.11.4 Conditional distributions of residuals

If our Gaussian linear regression model is correct, the residuals e_i and standardized residuals r_i should have:

- an approximately Gaussian distribution, with:
- a mean of 0
- a constant variance

This should be true **regardless** of the value of X.

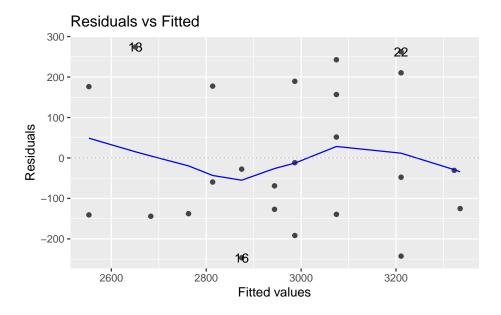

But if we didn't correctly guess the functional form of linear component of the mean,

$$\mathrm{E}[Y|X=x] = \beta_0 + \beta_1 X_1 + \ldots + \beta_p X_p$$

Then the the residuals might have nonzero mean or nonconstant variance for some values of x.

0.11.4.1 Residuals versus fitted values

To look for these issues, we can plot the residuals e_i against the fitted values \hat{y}_i :

If the model is correct, the blue line should stay flat and close to 0, and the cloud of dots should have the same vertical spread regardless of the fitted value.

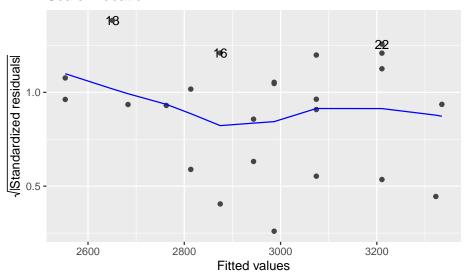

If not, we probably need to change the functional form of linear component of the mean,

$$E[Y|X = x] = \beta_0 + \beta_1 X_1 + ... + \beta_p X_p$$

0.11.4.2 Scale-location plot

We can also plot the square roots of the absolute values of the standardized residuals against the fitted values:

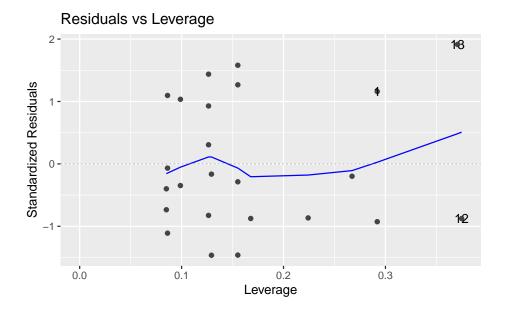

Scale-Location

Here, the blue line doesn't need to be near 0, but it should be flat. If not, the residual variance σ^2 might not be constant, and we might need to transform our outcome Y (or use a model that allows non-constant variance).

0.11.4.3 Residuals versus leverage

We can also plot our standardized residuals against "leverage", which roughly speaking is a measure of how unusual each x_i value is. Very unusual x_i values can have extreme effects on the model fit, so we might want ot remove those observations as outliers, particularly if they have large residuals.

The blue line should be relatively flat and close to 0 here.

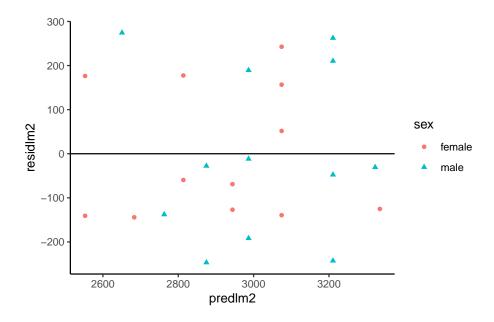

0.11.5 Diagnostics constructed by hand

```
bw =
  bw |>
mutate(
  predlm2 = predict(bw_lm2),
  residlm2 = weight - predlm2,
  std_resid = residlm2 / sigma(bw_lm2),
  # std_resid_builtin = rstandard(bw_lm2), # uses leverage
  sqrt_abs_std_resid = std_resid |> abs() |> sqrt()
)
```

Residuals vs fitted

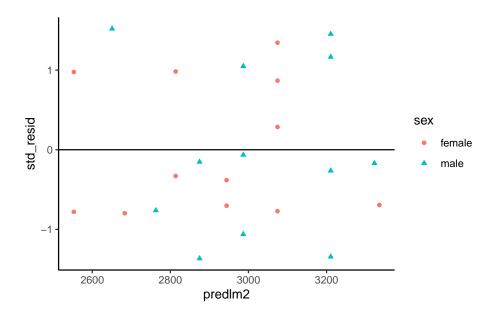

```
resid_vs_fit = bw |>
    ggplot(
    aes(x = predlm2, y = residlm2, col = sex, shape = sex)
) +
    geom_point() +
    theme_classic() +
    geom_hline(yintercept = 0)

print(resid_vs_fit)
```

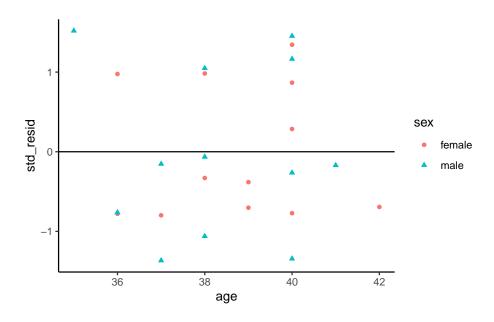

Standardized residuals vs fitted

```
bw |>
    ggplot(
    aes(x = predlm2, y = std_resid, col = sex, shape = sex)
) +
    geom_point() +
    theme_classic() +
    geom_hline(yintercept = 0)
```

Standardized residuals vs gestational age

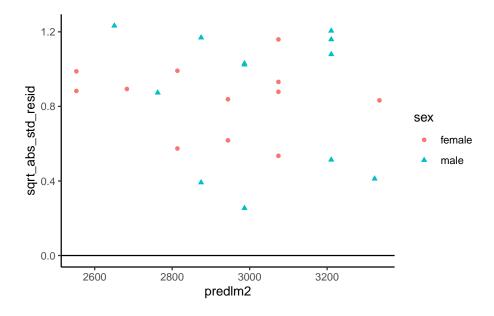

```
bw |>
    ggplot(
    aes(x = age, y = std_resid, col = sex, shape = sex)
) +
    geom_point() +
    theme_classic() +
    geom_hline(yintercept = 0)
```

sqrt(abs(rstandard())) vs fitted

Compare with autoplot(bw_lm2, 3)

```
bw |>
    ggplot(
    aes(x = predlm2, y = sqrt_abs_std_resid, col = sex, shape = sex)
) +
    geom_point() +
    theme_classic() +
    geom_hline(yintercept = 0)
```

0.12 Model selection

If we have a lot of covariates in our dataset, we might want to choose a small subset to use in our model.

There are a few possible metrics to consider for choosing a "best" model.

0.12.1 Mean squared error

We might want to minimize the **mean squared error**, $\mathrm{E}[(y-\hat{y})^2]$, for new observations that weren't in our data set when we fit the model.

Unfortunately,

$$\frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

gives a biased estimate of $\mathrm{E}[(y-\hat{y})^2]$ for new data. If we want an unbiased estimate, we will have to be clever.

0.12.2 Cross-validation

```
data("carbohydrate", package = "dobson")
library(cvTools)
full.model <- lm(carbohydrate ~ ., data = carbohydrate)
temp =
   cvFit(full.model, data = carbohydrate, K = 5, R = 10,
y = carbohydrate$carbohydrate)</pre>
```

0.13 Categorical covariates with more than two levels

0.13.1

In the birthweight example, the variable sex had only two observed values:

```
unique(bw$sex)
```

[1] "female" "male"

If there are more than two observed values, we can't just use a single variable with 0s and 1s.

0.13.2

For example, here's the (in)famous iris data:

```
iris |> tibble()
```

# A tibble: 150 x 5	# .	A t	ibb	le	: 1	50	X	5
---------------------	-----	-----	-----	----	-----	----	---	---

	Sepal.Length	${\tt Sepal.Width}$	Petal.Length	${\tt Petal.Width}$	Species

```

0.13.3

There are three species:

```
iris$Species |> unique()

[1] setosa versicolor virginica
Levels: setosa versicolor virginica
```

0.13.4

If we want to model Sepal.Length by species, we could create a variable X that represents "setosa" as X=1, "virginica" as X=2, and "versicolor" as X=3.

Then we could fit a model like:

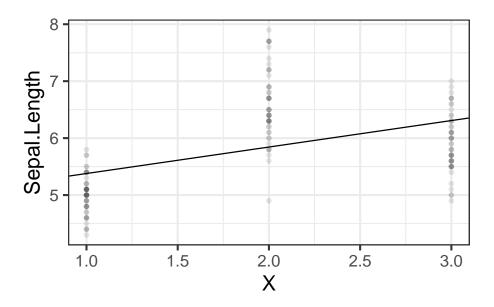

```
iris_lm1 = lm(Sepal.Length ~ X, data = iris)
iris_lm1 |> parameters() |> print_md()
```

Parameter	Coefficient	SE	95% CI	t(148)	p
$\overline{ ext{(Intercept)}}$	4.91 0.47		(4.60, 5.23) (0.32, 0.61)		

0.13.5 Let's see how that model looks:

```
iris_plot1 = iris |>
  ggplot(
    aes(
        x = X,
        y = Sepal.Length)
) +
  geom_point(alpha = .1) +
  geom_abline(
  intercept = coef(iris_lm1)[1],
    slope = coef(iris_lm1)[2]) +
  theme_bw(base_size = 18)
```

print(iris_plot1)

We have forced the model to use a straight line for the three estimated means. Maybe not a good idea?

0.13.6 Let's see what R does with categorical variables by default:

```
iris_lm2 = lm(Sepal.Length ~ Species, data = iris)
iris_lm2 |> parameters() |> print_md()
```

Parameter	Coefficient	SE	95% CI	t(147)	p
(Intercept)	5.01	0.07	(4.86, 5.15)	68.76	< .001
Species	0.93	0.10	(0.73, 1.13)	9.03	< .001
(versicolor)					
Species (virginica)	1.58	0.10	(1.38, 1.79)	15.37	< .001

0.13.7 Re-parametrize with no intercept

If you don't want the default and offset option, you can use "-1" like we've seen previously:

```
iris.lm2b = lm(Sepal.Length ~ Species - 1, data = iris)
iris.lm2b |> parameters() |> print_md()
```

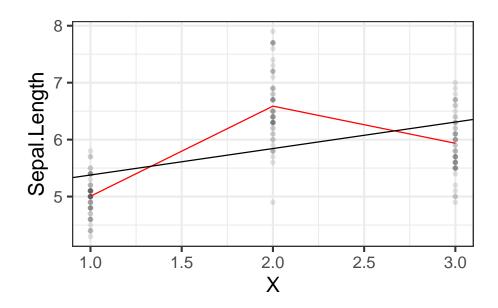

Parameter	Coefficient	SE	95% CI	t(147)	p
Species (setosa)	5.01	0.07	(4.86, 5.15)	68.76	< .001
Species	5.94	0.07	(5.79, 6.08)	81.54	< .001
(versicolor)					
Species (virginica)	6.59	0.07	(6.44, 6.73)	90.49	< .001

0.13.8 Let's see what these new models look like:

```
iris_plot2 =
  iris |>
  mutate(
    predlm2 = predict(iris_lm2)) |>
  arrange(X) |>
  ggplot(aes(x = X, y = Sepal.Length)) +
  geom_point(alpha = .1) +
```

```
geom_line(aes(y = predlm2), col = "red") +
geom_abline(
   intercept = coef(iris_lm1)[1],
   slope = coef(iris_lm1)[2]) +
theme_bw(base_size = 18)

print(iris_plot2)
```

0.13.9 Let's see how R did that:

```
formula(iris_lm2)
```

Sepal.Length ~ Species

This is called a "corner point parametrization".

```
formula(iris.lm2b)
```

Sepal.Length ~ Species - 1

```
model.matrix(iris.lm2b) |> as_tibble() |> unique()
```

A tibble: 3 x 3

 Speciessetosa
 Speciesversicolor

0.15 Risk Estimation and Prediction

Logistic regression is a method for estimating and predicting the probability of a *binary outcome variable* using one or more *predictors* (a.k.a. *covariates*).

Definition 0.1 (binary variable). A **binary variable** is a random variable which has only two possible values (such as diseased/healthy) in its range.

Exercise 0.1. Recall: what kind of outcome is linear regression used for?

Solution. Linear regression is typically used for continuous outcomes.

You have already seen methods for predicting binary outcomes using one predictor that is also binary (such as exposure/non-exposure).

We will first review one-predictor analyses, with a special focus on risk ratios and odds ratios, which are important concepts for interpreting logistic regression.

Example 0.1 (Oral Contraceptive Use and Heart Attack).

• Research question: does oral contraceptive (OC) use affect the risk of myocardial infarction (MI; a.k.a. heart attack)?

This was an issue when oral contraceptives were first developed, because the original formulations used higher concentrations of hormones. Modern OCs don't have this issue.

Table 16 contains simulated data for an imaginary follow-up (a.k.a. *prospective*) study in which two groups are identified, one using OCs and another not using OCs, and both groups are tracked for three years to determine how many in each groups have MIs.

```
library(dplyr)
oc_mi =
  tribble(
    ~OC, ~MI, ~Total,
    "OC use", 13, 5000,
    "No OC use", 7, 10000
) |>
  mutate(`No MI` = Total - MI) |>
  relocate(`No MI`, .after = MI)

totals =
  oc_mi |>
  summarize(across(c(MI, `No MI`, Total), sum)) |>
  mutate(OC = "Total")

oc_mi = bind_rows(oc_mi, totals)

pander(oc_mi)
```

Table 16: Simulated data from study of oral contraceptive use and heart attack risk

OC	MI	No MI	Total
OC use	13	4,987	5,000

Generalized Linear Models

OC	MI	No MI	Total
No OC use	7	9,993	10,000
Total	20	14,980	15,000

Exercise 0.2. Review: estimate the probabilities of MI for OC users and non-OC users in Example 0.1.

Solution.

$$\hat{p}(MI|OC) = \frac{13}{5000} = 0.0026$$

$$\hat{p}(MI|\neg OC) = \frac{7}{10000} = 7 \times 10^{-4}$$

i Two meanings of "controls"

Depending on context, "controls" can mean either individuals who don't experience an *exposure* of interest, or individuals who don't experience an *outcome* of interest.

Definition 0.2 (cases and controls in retrospective studies). In *retrospective studies*, participants who experience the outcome of interest are called **cases**, while participants who don't experience that outcome are called **controls**.

Definition 0.3 (treatment groups and control groups in prospective studies). In *prospective studies*, the group of participants who experience the treatment or exposure of interest is called the **treatment group**, while the participants who receive the baseline or comparison treatment (for example, clinical trial participants who receive a placebo or a standard-of-care treatment rather than an experimental treatment) are called **controls**.

0.15.1 Comparing probabilities

0.15.1.1 Risk differences

The simplest comparison of two probabilities, π_1 , and π_2 , is the difference of their values:

Definition 0.4 (Risk difference). The **risk difference** of two probabilities, π_1 , and π_2 , is the difference of their values:

$$\delta(\pi_1,\pi_2) \stackrel{\mathrm{def}}{=} \pi_1 - \pi_2$$

Example 0.2. In Example 0.1, the estimated risk difference in MI risk between OC users and OC non-users is:

$$\begin{split} \hat{\delta}(\pi(OC), \pi(\neg OC)) &= \delta(\hat{\pi}(OC), \hat{\pi}(\neg OC)) \\ &= \hat{\pi}(OC) - \hat{\pi}(\neg OC) \\ &= 0.0026 - 7 \times 10^{-4} \\ &= 0.0019 \end{split}$$

0.15.1.2 Risk ratios

Definition 0.5 (Relative risk ratios). The **relative risk** of two probabilities π_1 and π_2 , also called the **risk ratio**, is the ratio of those probabilities:

$$\rho(\pi_1,\pi_2)=\frac{\pi_1}{\pi_2}$$

Example 0.3. Above, we estimated that:

$$\hat{p}(MI|OC) = 0.0026$$

$$\hat{p}(MI|\neg OC) = 7 \times 10^{-4}$$

So we might estimate that the $relative\ risk$ of MI for OC versus non-OC is:

$$\begin{split} \hat{\rho}(OC, \neg OC) &= \frac{\hat{p}(MI|OC)}{\hat{p}(MI|\neg OC)} \\ &= \frac{0.0026}{7 \times 10^{-4}} \\ &= 3.7143 \end{split}$$

Both risk differences and risk ratios are defined by two probabilities, plus a choice of which probability is the **baseline** or **reference** probability (i.e., which probability is the subtrahend of the risk difference or the denominator of the risk ratio). To switch which one is the reference probability, invert the ratio and multiply the difference by -1.

Example 0.4. Above, we estimated that the risk ratio of OC versus non-OC is:

$$\rho(OC, \neg OC) = 3.7143$$

In comparison, the risk ratio for non-OC versus OC is:

$$\begin{split} \rho(\neg OC, OC) &= \frac{\hat{p}(MI|\neg OC)}{\hat{p}(MI|OC)} \\ &= \frac{7\times 10^{-4}}{0.0026} \\ &= 0.2692 \\ &= \frac{1}{\rho(OC, \neg OC)} \end{split}$$

0.15.2 Odds and probabilities

In logistic regression, we will make use of a transformation (rescaling) of probability, called odds.

Definition 0.6 (Odds). The **odds** of an outcome, denoted ω ("omega"), is the probability that the outcome occurs, divided by the probability that it doesn't occur.

That is, if the probability of an outcome is π , then the corresponding odds of that outcome is

$$\omega(\pi) \stackrel{\text{def}}{=} \frac{\pi}{1 - \pi}$$

This function, which transforms probabilities into odds, is called the **odds** function (see Figure 9).

```
odds = function(pi) pi/(1-pi)
library(ggplot2)
odds_plot = ggplot() +
  geom_function(fun = odds, aes(col = "odds function")) +
  xlim(0, .5) +
  xlab("Probability") +
  ylab("Odds") +
  geom_abline(aes(intercept = 0, slope = 1, col = "y=x")) +
  theme_bw()
print(odds_plot)
```

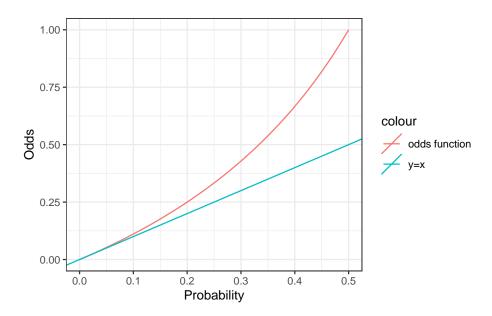

Figure 9: Odds versus probability

Example 0.5 (Calculating odds). In Exercise 0.2, we estimated that the probability of MI, given OC use, is $\pi(OC) \stackrel{\text{def}}{=} \Pr(MI|OC) = 0.0026$. If this estimate is correct, then the odds of MI, given OC use, is:

$$\omega(OC) \stackrel{\text{def}}{=} \frac{\Pr(MI|OC)}{\Pr(\neg MI|OC)}$$

$$= \frac{\Pr(MI|OC)}{1 - \Pr(MI|OC)}$$

$$= \frac{\pi(OC)}{1 - \pi(OC)}$$

$$= \frac{0.0026}{1 - 0.0026}$$

$$= 0.0026$$

Exercise 0.3 (Calculating odds). Estimate the odds of MI, for non-OC users.

Solution.

$$\omega_(\neg OC) = 7.0049 \times 10^{-4}$$

0.15.2.1 A shortcut for calculating odds

The usual estimate for a probability of an event is "# events/# observations". We often denote # events as x and # observations as n. So:

$$\hat{\pi} = \frac{x}{n}$$

Thus, the usual estimate for the probability of a nonevent is:

$$1 - \hat{\pi} = 1 - \frac{x}{n}$$
$$= \frac{n}{n} - \frac{x}{n}$$
$$= \frac{n - x}{n}$$

Thus, the estimated odds is:

$$\frac{\hat{\pi}}{1 - \hat{\pi}} = \frac{\left(\frac{x}{n}\right)}{\left(\frac{n-x}{n}\right)} = \frac{x}{n-x}$$

That is, odds can be calculated directly as "# events" divided by "# nonevents" (without needing to calculate $\hat{\pi}$ and $1 - \hat{\pi}$ first).

Example 0.6 (calculating odds using the shortcut). In Example 0.5, we calculated

$$\omega(OC) = 0.0026$$

Let's recalculate this result using our shortcut:

$$\omega(OC) = \frac{13}{5000 - 13}$$
$$= 0.0026$$

Same answer!

0.15.2.2 Odds of rare events

For rare events (small π), odds and probabilities are nearly equal, because $1 - \pi \approx 1$ (see Figure 9).

For example, in Example 0.5, the probability and odds differ by 6.7776×10^{-6} .

Exercise 0.4. What odds value corresponds to the probability $\pi = 0.2$, and what is the numerical difference between these two values?

Solution.

$$\omega = \frac{\pi}{1 - \pi} = \frac{.2}{.8} = .25$$

0.15.3 The inverse odds function

Definition 0.7 (inverse odds function). The inverse odds function,

$$\pi(\omega) \stackrel{\mathrm{def}}{=} \frac{\omega}{1+\omega}$$

converts odds into their corresponding probabilities (Figure 10).

The inverse-odds function takes an odds as input and produces a probability as output. Its domain of inputs is $[0, \infty)$ and its range of outputs is [0, 1].

```
odds_inv = function(omega) omega / (1 + omega)
ggplot() +

geom_function(fun = odds_inv, aes(col = "inverse-odds")) +
    xlab("Odds") +
    ylab("Probability") +
    xlim(0,5) +
    ylim(0,1) +
    geom_abline(aes(intercept = 0, slope = 1, col = "x=y"))
```

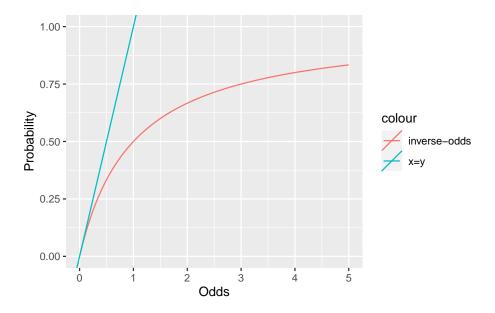

Figure 10: The inverse odds function, $\pi(\omega)$

Important

An equivalent expression for the inverse odds function is

$$\pi(\omega)=(1-\omega^{-1})^{-1}$$

.

Exercise 0.5. Prove that the expression above is equivalent to Definition 0.7.

Exercise 0.6. What probability corresponds to an odds of $\omega = 1$, and what is the numerical difference between these two values?

Solution.

$$\pi(1) = \frac{1}{1+1} = \frac{1}{2} = .5$$

$$1 - \pi(1) = 1 - .5 = .5$$

0.15.4 Odds ratios

Now that we have defined odds, we can introduce another way of comparing event probabilities: odds ratios.

Definition 0.8 (Odds ratio). The **odds ratio** for two odds ω_1 , ω_2 is their ratio:

$$\theta(\omega_1,\omega_2) = \frac{\omega_1}{\omega_2}$$

Example 0.7 (Calculating odds ratios). In Example 0.1, the odds ratio for OC users versus OC-non-users is:

$$\theta(\omega(OC), \omega(\neg OC)) = \frac{\omega(OC)}{\omega(\neg OC)}$$
$$= \frac{0.0026}{7 \times 10^{-4}}$$
$$= 3.7143$$

When the outcome is rare (i.e., its probability is small) for both groups being compared in an odds ratio, the odds of the outcome will be similar to the probability of the outcome, and thus the risk ratio will be similar to the odds ratio.

For example, in Example 0.1, the outcome is rare for both OC and non-OC participants, so the odds for both groups are similar to the corresponding probabilities, and the odds ratio is similar the risk ratio.

0.15.4.1 A shortcut for calculating odds ratio estimates

The general form of a two-by-two table is shown in Table 17.

Table 17: A generic 2x2 table

Event	Non-Event	Total
a	b	a+b
\mathbf{c}	d	c+d
a+c	b+d	a+b+c+d
	a c	c d

From this table, we have:

• $\hat{\pi}(Event|Exposed) = a/(a+b)$

- $\hat{\pi}(\neg Event|Exposed) = b/(a+b)$
- $\hat{\omega}(Event|Exposed) = \frac{\left(\frac{a}{a+b}\right)}{\left(\frac{b}{a+b}\right)} = \frac{a}{b}$
- $\hat{\omega}(Event|\neg Exposed) = \frac{c}{d}$ (see Exercise 0.7)
- $\theta(Exposed, \neg Exposed) = \frac{\frac{a}{b}}{\frac{c}{d}} = \frac{ad}{bc}$

Exercise 0.7. Given Table 17, show that $\hat{\omega}(Event|\neg Exposed) = \frac{c}{d}$.

0.15.4.2 Properties of odds ratios

Odds ratios have a special property: we can swap a covariate with the outcome, and the odds ratio remains the same.

Example 0.8. In Example 0.1, we have:

$$\theta(MI;OC) \stackrel{\text{def}}{=} \frac{\omega(MI|OC)}{\omega(MI|\neg OC)}$$

$$\stackrel{\text{def}}{=} \frac{\left(\frac{\Pr(MI|OC)}{\Pr(\neg MI|OC)}\right)}{\left(\frac{\Pr(MI|OC)}{\Pr(\neg MI|OC)}\right)}$$

$$= \frac{\left(\frac{\Pr(MI,OC)}{\Pr(\neg MI,OC)}\right)}{\left(\frac{\Pr(MI,OC)}{\Pr(\neg MI,OC)}\right)}$$

$$= \left(\frac{\Pr(MI,OC)}{\Pr(\neg MI,OC)}\right) \left(\frac{\Pr(\neg MI,\neg OC)}{\Pr(MI,\neg OC)}\right)$$

$$= \left(\frac{\Pr(MI,OC)}{\Pr(MI,\neg OC)}\right) \left(\frac{\Pr(\neg MI,\neg OC)}{\Pr(\neg MI,OC)}\right)$$

$$= \left(\frac{\Pr(OC,MI)}{\Pr(\neg OC,MI)}\right) \left(\frac{\Pr(\neg OC,\neg MI)}{\Pr(OC,\neg MI)}\right)$$

$$= \left(\frac{\Pr(OC|MI)}{\Pr(\neg OC|MI)}\right) \left(\frac{\Pr(\neg OC|\neg MI)}{\Pr(OC|\neg MI)}\right)$$

$$= \frac{\left(\frac{\Pr(OC|MI)}{\Pr(\neg OC|MI)}\right)}{\left(\frac{\Pr(OC|MI)}{\Pr(\neg OC|\neg MI)}\right)}$$

$$\stackrel{\text{def}}{=} \frac{\omega(OC|MI)}{\omega(OC|\neg MI)}$$

$$\stackrel{\text{def}}{=} \theta(OC;MI)$$

Exercise 0.8. For Table 17, show that $\hat{\theta}(Exposed, Unexposed) = \hat{\theta}(Event, \neg Event)$.

0.15.5 Effect of study design

Table 16 simulates a follow-up study in which two populations were followed and the number of MI's was observed. The risks are P(MI|OC) and P(MI|OC) and we can estimate these risks from the data.

But suppose we had a case-control study in which we had 100 women with MI and selected a comparison group of 100 women without MI (matched as groups on age, etc.). Then MI is not random, and we cannot compute P(MI|OC) and we cannot compute the risk ratio. However, the odds ratio however can be computed.

The disease odds ratio is the odds for the disease in the exposed group divided by the odds for the disease in the unexposed group, and we cannot validly compute and use these separate parts.

But we can validly compute and use the exposure odds ratio, which is the odds for exposure in the disease group divided by the odds for exposure in the non-diseased group (because exposure can be treated as random). And these two odds ratios are mathematically equivalent, as we saw in Section 0.15.4.2.

Exercise 0.9. Calculate the odds ratio of MI with respect to OC use, assuming that Table 16 comes from a case-control study. Confirm that the result is the same as in Example 0.7.

Solution. •
$$\omega(OC|MI) = P(OC|MI)/(1-P(OC|MI)) = \frac{13}{7} = 1.8571$$

•
$$\omega(OC|\neg MI) = P(OC|\neg MI)/(1-P(OC|\neg MI) = \frac{4987}{9993} = 0.499$$

•
$$\theta(OC, MI) = \frac{\omega(OC|MI)}{\omega(OC|\neg MI)} = \frac{13/7}{4987/9993} = 3.7214$$

This is the same estimate we calculated in Example 0.7.

0.15.5.1 Cross-Sectional Studies

- If a cross-sectional study is a probability sample of a population (which it rarely is) then we can estimate risks.
- If it is a sample, but not an unbiased probability sample, then we need to treat it in the same way as a case-control study.

- We can validly estimate odds ratios in either case.
- But we can usually not validly estimate risks and risk ratios.

0.16 Introduction to logistic regression

- In Example 0.1, we estimated the risk and the odds of MI for two discrete cases, as to whether of not the individual used oral contraceptives.
- If the predictor is quantitative (dose) or there is more than one predictor, the task becomes more difficult.
- In this case, we will use logistic regression, which is a generalization of the linear regression models you have been using that can account for a binary response instead of a continuous one.

0.16.1 Binary outcomes models - one group, no covariates

$$\begin{split} p(Y=1) &= \pi \\ p(Y=0) &= 1 - \pi \\ p(Y=y) &= \pi^y (1-\pi)^{1-y} \\ \mathbf{y} &= (y_1, ..., y_n) \\ \mathcal{L}(\pi; \mathbf{y}) &= \pi^{\sum y_i} (1-\pi)^{n-\sum y_i} \\ \ell(\pi, \mathbf{y}) &= \left(\sum y_i\right) \log \left\{\pi\right\} + \left(n - \sum y_i\right) \log \left\{1 - \pi\right\} \\ &= \left(\sum y_i\right) \left(\log \left\{\pi\right\} - \log \left\{1 - \pi\right\}\right) + n \cdot \log \left\{1 - \pi\right\} \\ &= \left(\sum y_i\right) \log \left\{\frac{\pi}{1-\pi}\right\} + n \cdot \log \left\{1 - \pi\right\} \end{split}$$

0.16.2 Binary outcomes - general

$$\begin{split} p(Y_i = 1) &= \pi_i \\ p(Y_i = 0) &= 1 - \pi_i \\ p(Y_i = y) &= (\pi_i)^y (1 - \pi_i)^{1 - y} \\ \mathbf{y} &= (y_1, ..., y_n) \\ \mathcal{L}(\pi; \mathbf{y}) &= \prod_{i=1}^n (\pi_i)^{y_i} (1 - \pi_i)^{1 - y_i} \\ \ell(\pi, \mathbf{y}) &= \sum_{i=1}^n y_i \log \left\{ \pi_i \right\} + (1 - y_i) \log \left\{ 1 - \pi_i \right\} \end{split}$$

0.16.3 Modeling π_i as a function of X_i

If there are only a few distinct X_i values, we can model each one separately.

Otherwise, we need regression.

$$\pi(x) \equiv \mathcal{E}(Y = 1|X = x)$$
$$= f(x^{\top}\beta)$$

Typically, we use $f(\eta) = \text{expit}(\eta)$.

Definition 0.9 (expit function). The **expit** function (Figure 11), also known as the **inverse-logit** or **logistic** function, is:

$$\begin{aligned} \operatorname{expit}(\eta) &\stackrel{\text{def}}{=} \frac{\exp \{\eta\}}{1 + \exp \{\eta\}} \\ &= (1 + \exp \{-\eta\})^{-1} \end{aligned}$$

```
expit = function(eta) exp(eta)/(1+exp(eta))
library(ggplot2)
expit_plot =
    ggplot() +
    geom_function(fun = expit) +
    xlim(-5, 5) +
    ylim(0,1) +
    ylab(expression(expit(eta))) +
    xlab(expression(eta)) +
    theme_bw()
print(expit_plot)
```

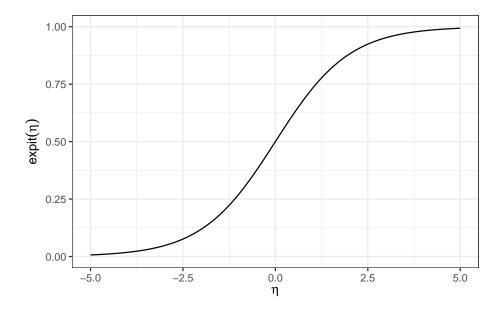

Figure 11: The expit function

Definition 0.10 (logit function). The inverse of the expit function is the

logit function:

$$g(p) = f^{-1}(p) = \mathrm{logit}(p) = \log\left\{\frac{p}{1-p}\right\}$$

```
logit = function(p) log(odds(p))

logit_plot =
    ggplot() +
    geom_function(fun = logit) +
    xlim(.01, .99) +
    ylab("logit(p)") +
    xlab("p") +
    theme_bw()
print(logit_plot)
```

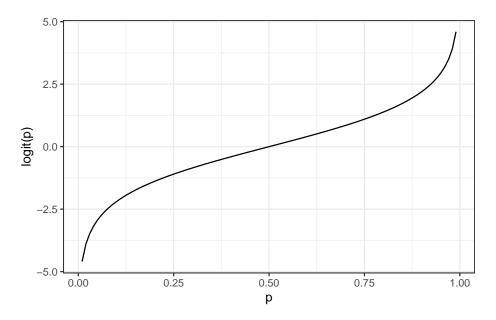

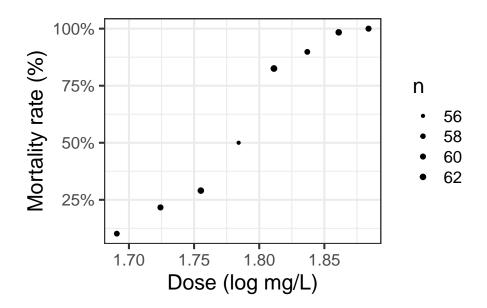

Figure 12: the logit function

0.16.4 Diagram of expit and logit

$$\left[\pi \stackrel{\text{def}}{=} \Pr(Y = 1)\right] \underbrace{\overbrace{\bigoplus_{\substack{1=-\omega\\1+\omega}}^{\frac{\pi}{1-m}}}_{\text{expit}(\eta)} \left[\omega \stackrel{\text{def}}{=} \operatorname{odds}(Y = 1)\right] \stackrel{\log\{\omega\}}{\underset{\text{exp}\{\eta\}}{\longleftarrow}} \left[\eta \stackrel{\text{def}}{=} \operatorname{log-odds}(Y = 1)\right]$$

0.16.5 Meet the beetles

```
library(glmx)
data(BeetleMortality, package = "glmx")
beetles = BeetleMortality |>
 mutate(
   pct = died/n,
    survived = n - died
  )
plot1 =
  beetles |>
  ggplot(aes(x = dose, y = pct)) +
  geom_point(aes(size = n)) +
  xlab("Dose (log mg/L)") +
  ylab("Mortality rate (%)") +
  scale_y_continuous(labels = scales::percent) +
  scale_size(range = c(1,2)) +
  theme_bw(base_size = 18)
print(plot1)
```

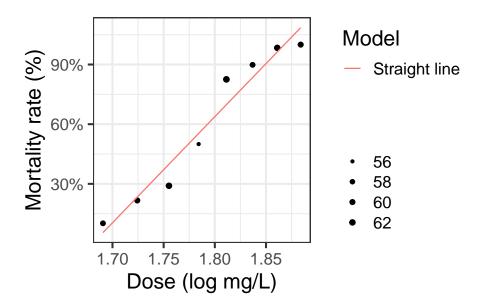

Mortality rates of adult flour beetles after five hours' exposure to gaseous carbon disulphide (Bliss 1935)

0.16.6 Why don't we use linear regression?

```
beetles_glm_grouped = beetles |>

```
9 1.69 6 59 0.102 53 0
10 1.69 6 59 0.102 53 0
# i 471 more rows
```

Here's the model with individual data

```
beetles_glm_ungrouped =
  beetles_long |>
  glm(
    formula = outcome ~ dose,
    family = "binomial")

beetles_glm_ungrouped |> parameters() |> print_md()
```

Parameter	Log-Odds	SE	95% CI	Z	р
(Intercept) dose	-60.72 34.27		(-71.44, -51.08) (28.85, 40.30)		

Here's the previous version again:

```
beetles_glm_grouped |> parameters() |> print_md()
```

Parameter	Log-Odds	SE	95% CI	Z	р
(Intercept) dose	-60.72 34.27		(-71.44, -51.08) (28.85, 40.30)		

They seem the same! But not quite:

```
logLik(beetles_glm_grouped)
```

```
'log Lik.' -18.72 (df=2)
logLik(beetles_glm_ungrouped)
```

'log Lik.' -186.2 (df=2)

The difference is due to the binomial coefficient $\binom{n}{x}$ which isn't included in the individual-observations (Bernoulli) version of the model.

0.17 Multiple logistic regression

0.17.1 Coronary heart disease (WCGS) study data

Let's use the data from the following study to explore multiple logistic regression:

0.17.1.1 Summary of study

From Vittinghoff et al 2012:

"The Western Collaborative Group Study (WCGS) was a large epidemiological study designed to investigate the association between the "type A" behavior pattern and coronary heart disease (CHD) (Rosenman et al. 1964)."

From Wikipedia, "Type A and Type B personality theory":

"The hypothesis describes Type A individuals as outgoing, ambitious, rigidly organized, highly status-conscious, impatient, anxious, proactive, and concerned with time management....

The hypothesis describes Type B individuals as a contrast to those of Type A. Type B personalities, by definition, are noted to live at lower stress levels. They typically work steadily and may enjoy achievement, although they have a greater tendency to disregard physical or mental stress when they do not achieve."

0.17.1.2 Study design

from ?faraway::wcgs:

3154 healthy young men aged 39-59 from the San Francisco area were assessed for their personality type. All were free from coronary heart disease at the start of the research. Eight and a half years later change in CHD status was recorded.

Details (from faraway::wcgs)

The WCGS began in 1960 with 3,524 male volunteers who were employed by 11 California companies. Subjects were 39 to 59 years old and free of heart disease as determined by electrocardiogram. After the initial screening, the study population dropped to 3,154 and the number of companies to 10 because of various exclusions. The cohort comprised both blue- and white-collar employees.

At baseline the following information was collected:

- socio-demographic including:
- age
- education
- marital status
- income
- occupation
- physical and physiological including:
- height
- weight

- blood pressure
- electrocardiogram
- corneal arcus;
- biochemical including:
- cholesterol and lipoprotein fractions;
- medical and family history and use of medications;
- behavioral data including
- Type A interview,
- smoking,
- exercise
- alcohol use.

Later surveys added data on:

- anthropometry
- triglycerides
- Jenkins Activity Survey
- caffeine use

Average follow-up continued for 8.5 years with repeat examinations.

Reference: Coronary Heart Disease in the Western Collaborative Group Study Final Follow-up Experience of 8 1/2 Years Ray H. Rosenman, MD; Richard J. Brand, PhD; C. David Jenkins, PhD; Meyer Friedman, MD; Reuben Straus, MD; Moses Wurm, MD JAMA. 1975;233(8):872-877. doi:10.1001/jama.1975.03260080034016.

0.17.2 Load the data

Here, I load the data:

```
## load the data directly from a UCSF website:
# library(haven)
# url = paste0(
```

```
# # I'm breaking up the url into two chunks for readability
# "https://regression.ucsf.edu/sites/g/files/",
# "tkssra6706/f/wysiwyg/home/data/wcgs.dta")
# wcgs = haven::read_dta(url)

# I presaved the data in my project's `data` folder
library(here) # provides the `here()` function
library(fs) # provides the `path()` function
here::here() |>
   fs::path('data/wcgs.rda') |>
   load()
```

0.17.3 Now let's do some data cleaning

```
library(arsenal) # provides `set_labels()`

wcgs = wcgs |>
    mutate(
    age = age |>
        arsenal::set_labels("Age (years)"),

arcus =
    arcus |>
    as.logical() |>
    arsenal::set_labels("Arcus Senilis"),

time169 =
    time169 |>
    as.numeric() |>
    arsenal::set_labels("Observation (follow up) time (days)"),
```

```
dibpat =
    dibpat |>
    as_factor() |>
    relevel(ref = "Type A") |>
    arsenal::set_labels("Behavioral Pattern"),
  typchd69 = typchd69 |>
    labelled(
      label = "Type of CHD Event",
      labels =
        c(
          "None" = 0,
          "infdeath" = 1,
          "silent" = 2,
          "angina" = 3)),
 \mbox{\tt\#} turn stata-style labelled variables in to R-style factors:
 across(
    where(is.labelled),
   haven::as_factor)
)
```

0.17.4 What's in the data

Here's a table of the data:

```
wcgs |>
select(-c(id, uni, t1)) |>
tableby(chd69 ~ ., data = _) |>
summary(
pfootnote = TRUE,
```

title =
 "Baseline characteristics by CHD status at end of follow-up")

0.17.5 Data by age and personality type

For now, we will look at the interaction between age and personality type (dibpat). To make it easier to visualize the data, we summarize the event rates for each combination of age:

```
chd_grouped_data =
  wcgs |>
  summarize(
    .by = c(age, dibpat),
    n = n(),
    `p(chd)` = mean(chd69 == "Yes") |>
        labelled(label = "CHD Event by 1969"),
    `odds(chd)` = `p(chd)`/(1-`p(chd)`),
    `logit(chd)` = log(`odds(chd)`)
)

chd_grouped_data
```

A tibble: 42×6

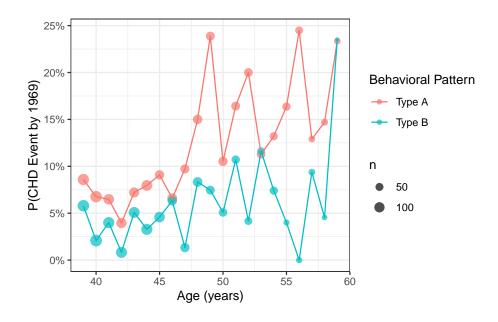

```
n `p(chd)`
                                 `odds(chd)` `logit(chd)`
     age dibpat
   <dbl> <fct> <int> <dbl+lbl>
                                       <dbl>
                                                     <dbl>
                   76 0.105
                                                     -2.14

0.17.7 Logistic regression models for CHD data

Here, we fit stratified models for CHD by personality type.

```
chd_glm_strat = glm(
   "formula" = chd69 == "Yes" ~ dibpat + dibpat:age - 1,
   "data" = wcgs,
   "family" = binomial(link = "logit")
)
chd_glm_strat |> parameters() |> print_md()
```

Generalized Linear Models

	Log-				
Parameter	Odds	SE	95% CI	${f z}$	p
dibpat (Type A)	-5.50	0.67	(-6.83, -4.19)	-8.18	< .001
dibpat (Type B)	-5.80	0.98	(-7.73, -3.90)	-5.95	< .001
dibpat (Type A) \times	0.07	0.01	(0.05, 0.10)	5.24	< .001
age					
dibpat (Type B) \times	0.06	0.02	(0.02, 0.10)	3.01	0.003
age					

We can get the corresponding odds ratios $(e^{\beta}s)$ by passing exponentiate = TRUE to parameters():

```
chd_glm_strat |>
  parameters(exponentiate = TRUE) |>
  print_md()
```

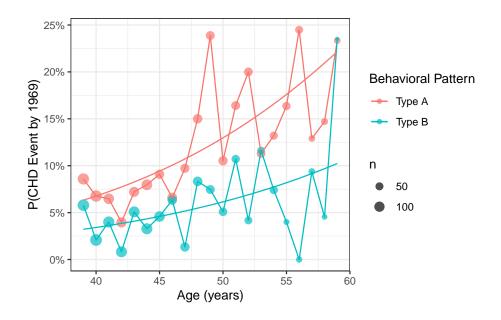

Parameter	Odds Ratio	SE	95% CI	${f z}$	p

dibpat (Type A)	1.07	0.01	(1.05, 1.10)	5.24	<
\times age					.001
dibpat (Type B)	1.06	0.02	(1.02, 1.11)	3.01	0.003
\times age					

0.17.8 Models superimposed on data

We can graph our fitted models on each scale (probability, odds, log-odds).

0.17.8.1 probability scale

```
curve_type_A = function(x)
  chd_glm_strat |> predict(
   type = "response",
    newdata = tibble(age = x, dibpat = "Type A"))
}
curve_type_B = function(x)
  chd_glm_strat |> predict(
    type = "response",
    newdata = tibble(age = x, dibpat = "Type B"))
}
chd_plot_probs_2 =
  chd_plot_probs +
  geom_function(
   fun = curve_type_A,
   aes(col = "Type A")
  geom_function(
   fun = curve_type_B,
    aes(col = "Type B")
  )
print(chd_plot_probs_2)
```

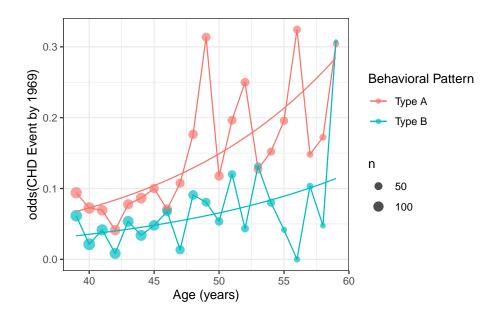

0.17.8.2 odds scale

```
curve_type_A = function(x)
{
   chd_glm_strat |> predict(
      type = "link",
      newdata = tibble(age = x, dibpat = "Type A")) |> exp()
}
curve_type_B = function(x)
{
   chd_glm_strat |> predict(
      type = "link",
      newdata = tibble(age = x, dibpat = "Type B")) |> exp()
}
```

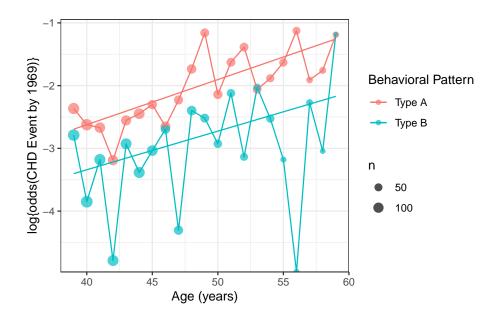

```
chd_plot_odds_2 =
  chd_plot_odds +
  geom_function(
   fun = curve_type_A,
    aes(col = "Type A")
) +
  geom_function(
  fun = curve_type_B,
   aes(col = "Type B")
)
```

print(chd_plot_odds_2)

0.17.8.3 log-odds (logit) scale

```
curve_type_A = function(x)
  chd_glm_strat |> predict(
   type = "link",
    newdata = tibble(age = x, dibpat = "Type A"))
}
curve_type_B = function(x)
  chd_glm_strat |> predict(
    type = "link",
    newdata = tibble(age = x, dibpat = "Type B"))
}
chd_plot_logit_2 =
  chd_plot_logit +
  geom_function(
    fun = curve_type_A,
    aes(col = "Type A")
 ) +
  geom_function(
   fun = curve_type_B,
    aes(col = "Type B")
  )
print(chd_plot_logit_2)
```

0.17.9 reference-group and contrast parametrization

We can also use the corner-point parametrization (with reference groups and contrasts):

```
chd_glm_contrasts =
  wcgs |>
  glm(
    "data" = _,
    "formula" = chd69 == "Yes" ~ dibpat*age,
    "family" = binomial(link = "logit")
)

chd_glm_contrasts |>
  parameters() |>
```

print_md()

	Log-				
Parameter	Odds	SE	95% CI	${f z}$	p
(Intercept)	-5.50	0.67	(-6.83, -4.19)	-8.18	< .001
dibpat (Type B)	-0.30	1.18	(-2.63, 2.02)	-0.26	0.797
age	0.07	0.01	(0.05, 0.10)	5.24	< .001
dibpat (Type B) \times	-0.01	0.02	(-0.06, 0.04)	-0.42	0.674
age					

Compare with what we had before:

```
chd_glm_strat |>
  parameters() |>
  print_md()
```

	т.				
Parameter	$rac{ m Log-}{ m Odds}$	\mathbf{SE}	95% CI	\mathbf{z}	n
	Odds	DL	3070 C1	<u> </u>	p
dibpat (Type A)	-5.50	0.67	(-6.83, -4.19)	-8.18	< .001
dibpat (Type B)	-5.80	0.98	(-7.73, -3.90)	-5.95	< .001
dibpat (Type A) \times	0.07	0.01	(0.05, 0.10)	5.24	< .001
age					
dibpat (Type B) \times	0.06	0.02	(0.02, 0.10)	3.01	0.003
age					

If I give you model 1, how would you get the coefficients of model 2?

0.18 Fitting logistic regression models

0.18.1

In general, the estimating equation $\ell'(\beta; \mathbf{x}) = 0$ cannot be solved analytically.

Instead, we have to use a variant of the Newton-Raphson method, which was discussed briefly in Epi 203. We won't go over it in this class; if you need to learn it, see Chapter 4 of Dobson and Barnett.

For now, all you need to know is that we make an iterative series of guesses, and each guess helps us make the next guess better (higher log-likelihood).

You can see some information about this process like so:

```
options(digits = 8)
temp =
  wcgs |>
  glm(
    control = glm.control(trace = TRUE),
    "data" = _,
    "formula" = chd69 == "Yes" ~ dibpat*age,
    "family" = binomial(link = "logit")
)
```

```
Deviance = 1775.7899 Iterations - 1
Deviance = 1708.5396 Iterations - 2
Deviance = 1704.0434 Iterations - 3
Deviance = 1703.9833 Iterations - 4
Deviance = 1703.9832 Iterations - 5
Deviance = 1703.9832 Iterations - 6
```

After each iteration of the fitting procedure, the deviance $(2(\ell_{\text{full}} - \ell(\hat{\beta})))$ is printed. You can see that the algorithm took six iterations to converge to a solution where the likelihood wasn't changing much anymore.

0.19 Model comparisons for logistic models

0.19.1 Deviance test

We can compare the maximized log-likelihood of our model, $\ell(\hat{\beta}; \mathbf{x})$, versus the log-likelihood of the full model (aka saturated model aka maximal model), ℓ_{full} , which has one parameter per covariate pattern. With enough data, $2(\ell_{\text{full}} - \ell(\hat{\beta}; \mathbf{x})) \dot{\sim} \chi^2(N-p)$, where N is the number of distinct covariate patterns and p is the number of β parameters in our model. A significant p-value for this **deviance** statistic indicates that there's some detectable pattern in the data that our model isn't flexible enough to catch.

S

Caution

The deviance statistic needs to have a large amount of data **for each covariate pattern** for the χ^2 approximation to hold. A guideline from Dobson is that if there are q distinct covariate patterns $x_1...,x_q$, with $n_1,...,n_q$ observations per pattern, then the expected frequencies $n_k \cdot \pi(x_k)$ should be at least 1 for every pattern $k \in 1:q$.

If you have covariates measured on a continuous scale, you may not be able to use the deviance tests to assess goodness of fit.

0.19.2 Hosmer-Lemeshow test

If our covariate patterns produce groups that are too small, a reasonable solution is to make bigger groups by merging some of the covariate-pattern

groups together.

Hosmer and Lemeshow (1980) proposed that we group the patterns by their predicted probabilities according to the model of interest. For example, you could group all of the observations with predicted probabilities of 10% or less together, then group the observations with 11%-20% probability together, and so on; g=10 categories in all.

Then we can construct a statistic

$$X^2 = \sum_{c=1}^g \frac{(o_c - e_c)^2}{e_c}$$

where o_c is the number of events observed in group c, and e_c is the number of events expected in group c (based on the sum of the fitted values $\hat{\pi}_i$ for observations in group c).

If each group has enough observations in it, you can compare X^2 to a χ^2 distribution; by simulation, the degrees of freedom has been found to be approximately g-2.

For our CHD model, this procedure would be:

```
wcgs =
wcgs |>
mutate(
    pred_probs_glm1 = chd_glm_strat |> fitted(),
    pred_prob_cats1 =
        pred_probs_glm1 |>
        cut(breaks = seq(0, 1, by = .1),
            include.lowest = TRUE))

HL_table =
wcgs |>
summarize(
.by = pred_prob_cats1,
```

```
n = n(),
o = sum(chd69 == "Yes"),
e = sum(pred_probs_glm1)
)

HL_table |> pander()
```

pred_prob_cats1	n	0	e
(0.1, 0.2]	785	116	108
(0.2, 0.3]	64	12	13.77
[0,0.1]	$2,\!305$	129	135.2

[1] 1.1102871

```
pval1 = pchisq(X2, lower = FALSE, df = nrow(HL_table) - 2)
```

Our statistic is $X^2 = 1.1103$; $p(\chi^2(1) > 1.1103) = 0.292$, which is our p-value for detecting a lack of goodness of fit.

Unfortunately that grouping plan left us with just three categories with any observations, so instead of grouping by 10% increments of predicted probability, typically analysts use deciles of the predicted probabilities:

```
wcgs =
 wcgs |>
 mutate(
   pred_probs_glm1 = chd_glm_strat |> fitted(),
   pred_prob_cats1 =
     pred_probs_glm1 |>
      cut(breaks = quantile(pred_probs_glm1, seq(0, 1, by = .1)),
          include.lowest = TRUE))
HL_table =
 wcgs |>
 summarize(
   .by = pred_prob_cats1,
   n = n(),
   o = sum(chd69 == "Yes"),
   e = sum(pred_probs_glm1)
  )
HL_table |> pander()
```

pred_prob_cats1	n	O	e
(0.114, 0.147]	275	48	36.81
(0.147, 0.222]	314	51	57.19
(0.0774, 0.0942]	371	27	32.56
(0.0942, 0.114]	282	30	29.89
(0.0633, 0.069]	237	17	15.97
(0.069, 0.0774]	306	20	22.95
(0.0487, 0.0633]	413	27	24.1
(0.0409, 0.0487]	310	14	14.15
$[0.0322,\!0.0363]$	407	16	13.91
(0.0363, 0.0409]	239	7	9.48

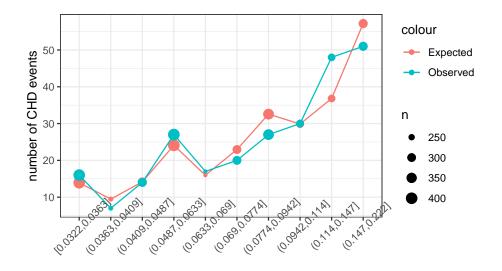

[1] 6.7811383

```
pval1 = pchisq(X2, lower = FALSE, df = nrow(HL_table) - 2)
```

Now we have more evenly split categories. The p-value is 0.5604, still not significant.

Graphically, we have compared:

```
HL_plot =
   HL_table |>
   ggplot(aes(x = pred_prob_cats1)) +
   geom_line(aes(y = e, x = pred_prob_cats1, group = "Expected", col = "Expected"))
   geom_point(aes(y = e, size = n, col = "Expected")) +
   geom_point(aes(y = o, size = n, col = "Observed")) +
   geom_line(aes(y = o, col = "Observed", group = "Observed")) +
   scale_size(range = c(1,4)) +
   theme_bw() +
   ylab("number of CHD events") +
   theme(axis.text.x = element_text(angle = 45))
```

pred_prob_cats1

0.19.3 Comparing models

- AIC = $-2 * \ell(\hat{\theta}) + 2 * p$ [lower is better]
- BIC = $-2 * \ell(\hat{\theta}) + p * \log(n)$ [lower is better]
- likelihood ratio [higher is better]

0.20 Residual-based diagnostics

0.20.1 Logistic regression residuals only work for grouped data

Residuals only work if there is more than one observation for most covariate patterns.

Here we will create the grouped-data version of our CHD model from the WCGS study:

```
wcgs_grouped =
  wcgs |>
  summarize(
    .by = c(dibpat, age),
    n = n(),
    chd = sum(chd69 == "Yes"),
    `!chd` = sum(chd69 == "No")
)

chd_glm_strat_grouped = glm(
    "formula" = cbind(chd, `!chd`) ~ dibpat + dibpat:age - 1,
    "data" = wcgs_grouped,
    "family" = binomial(link = "logit")
)

chd_glm_strat_grouped |> parameters() |> print_md()
```

	Log-				
Parameter	Odds	SE	95% CI	${f z}$	p
dibpat (Type A)	-5.50	0.67	(-6.83, -4.19)	-8.18	< .001
dibpat (Type B)	-5.80	0.98	(-7.73, -3.90)	-5.95	< .001
dibpat (Type A) \times	0.07	0.01	(0.05, 0.10)	5.24	< .001
age					
dibpat (Type B) \times	0.06	0.02	(0.02, 0.10)	3.01	0.003
age					

0.20.2 (Response) residuals

$$e_k \stackrel{\mathrm{def}}{=} \bar{y}_k - \hat{\pi}(x_k)$$

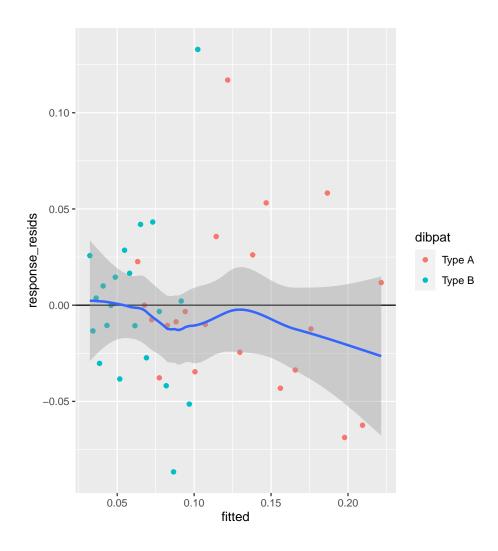

(k indexes the covariate patterns)

We can graph these residuals e_k against the fitted values $\hat{\pi}(x_k)$:

```
wcgs_grouped =
  wcgs_grouped |>
  mutate(
    fitted = chd_glm_strat_grouped |> fitted(),
    fitted_logit = fitted |> logit(),
    response_resids =
      chd_glm_strat_grouped |> resid(type = "response")
  )
wcgs_response_resid_plot =
  wcgs_grouped |>
  ggplot(
    mapping = aes(
     x = fitted,
      y = response_resids
    )
  ) +
  geom_point(
    aes(col = dibpat)
  ) +
  geom_hline(yintercept = 0) +
  geom_smooth( #<1>
    se = TRUE, \#<1>
   method.args = list( #<1>
      span=2/3, \#<1>
      degree=1, #<1>
      family="symmetric", #<1>
      iterations=3), #<1>
    method = stats::loess) #<1>
```

① Don't worry about these options for now; I chose them to match autoplot() as closely as I can. plot.glm and autoplot use stats::lowess instead of stats::lowess; stats::lowess is older, hard to use with geom_smooth, and hard to match exactly with stats::lowess; see https://support.bioconductor.org/p/2323/.]

wcgs_response_resid_plot |> print()

We can see a slight fan-shape here: observations on the right have larger variance (as expected since $var(\bar{y}) = \pi(1-\pi)/n$ is maximized when $\pi = 0.5$).

0.20.3 Pearson residuals

The fan-shape in the response residuals plot isn't necessarily a concern here, since we haven't made an assumption of constant residual variance, as we did for linear regression.

However, we might want to divide by the standard error in order to make the graph easier to interpret. Here's one way to do that:

The Pearson (chi-squared) residual for covariate pattern k is:

$$X_k = \frac{\bar{y}_k - \hat{\pi}_k}{\sqrt{\hat{\pi}_k (1 - \hat{\pi}_k)/n_k}}$$

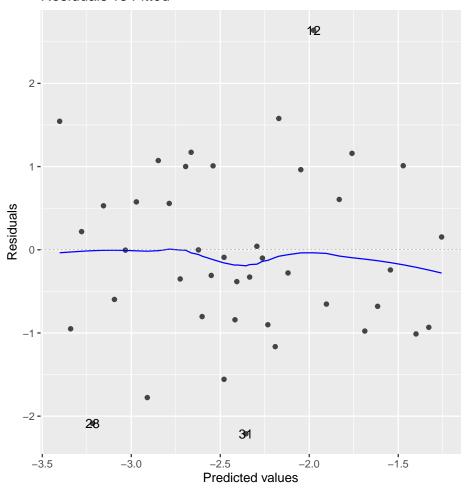

where

$$\begin{split} \hat{\pi}_k & \stackrel{\text{def}}{=} \hat{\pi}(x_k) \\ & \stackrel{\text{def}}{=} \hat{P}(Y = 1 | X = x_k) \\ & \stackrel{\text{def}}{=} \operatorname{expit}(x_i' \hat{\beta}) \\ & \stackrel{\text{def}}{=} \operatorname{expit}(\hat{\beta}_0 + \sum_{j=1}^p \hat{\beta}_j x_{ij}) \end{split}$$

Let's take a look at the Pearson residuals for our CHD model from the WCGS data (graphed against the fitted values on the logit scale):

```
library(ggfortify)
autoplot(chd_glm_strat_grouped, which = 1, ncol = 1) |> print()
```

Residuals vs Fitted

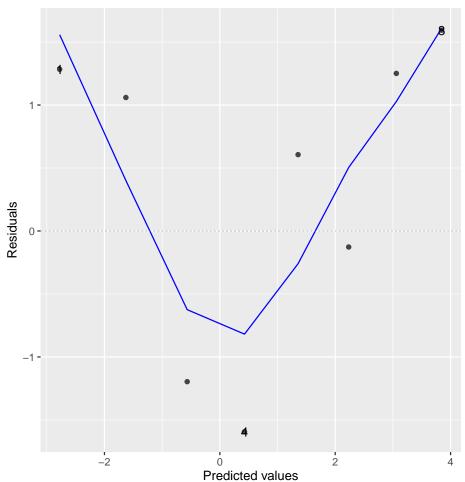

The fan-shape is gone, and these residuals don't show any obvious signs of model fit issues.

0.20.3.1 Pearson residuals plot for beetles data

If we create the same plot for the beetles model, we see some strong evidence of a lack of fit:

```
autoplot(beetles_glm_grouped, which = 1, ncol = 1) |> print()
```

Residuals vs Fitted

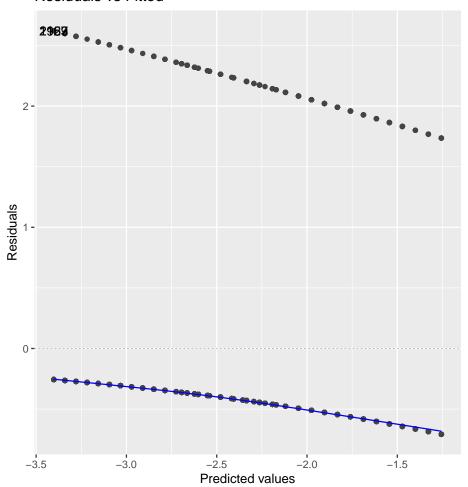

0.20.3.2 Pearson residuals with individual (ungrouped) data

What happens if we try to compute residuals without grouping the data by covariate pattern?

```
library(ggfortify)
autoplot(chd_glm_strat, which = 1, ncol = 1) |> print()
```

Residuals vs Fitted

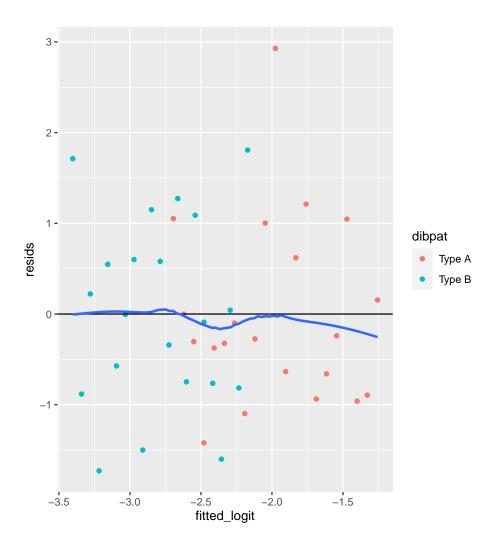

Meaningless.

0.20.3.3 Residuals plot by hand (optional section)

If you want to check your understanding of what these residual plots are, try building them yourself:

```
wcgs_grouped =
  wcgs_grouped |>
  mutate(
    fitted = chd_glm_strat_grouped |> fitted(),
    fitted_logit = fitted |> logit(),
    resids = chd_glm_strat_grouped |> resid(type = "pearson")
  )
wcgs_resid_plot1 =
  wcgs_grouped |>
  ggplot(
   mapping = aes(
     x = fitted_logit,
     y = resids
    )
  ) +
  geom_point(
    aes(col = dibpat)
  geom_hline(yintercept = 0) +
  geom_smooth(se = FALSE,
              method.args = list(
                span=2/3,
```

0.20.4 Pearson chi-squared goodness of fit test

The Pearson chi-squared goodness of fit statistic is:

$$X^2 = \sum_{k=1}^{m} X_k^2$$

Under the null hypothesis that the model in question is correct (i.e., sufficiently complex), $X^2 \sim \chi^2(N-p)$.

```
X = chd_glm_strat_grouped |>
    resid(type = "pearson")

chisq_stat = sum(X^2)

pval = pchisq(
    chisq_stat,
    lower = FALSE,
    df = length(X) - length(coef(chd_glm_strat_grouped)))
```

For our CHD model, the p-value for this test is 0.2652; no significant evidence of a lack of fit at the 0.05 level.

0.20.4.1 Standardized Pearson residuals

Especially for small data sets, we might want to adjust our residuals for leverage (since outliers in X add extra variance to the residuals):

$$r_{P_k} = \frac{X_k}{\sqrt{1-h_k}}$$

where h_k is the leverage of X_k . The functions autoplot() and plot.lm() use these for some of their graphs.

0.20.5 Deviance residuals

For large sample sizes, the Pearson and deviance residuals will be approximately the same. For small sample sizes, the deviance residuals from covariate patterns with small sample sizes can be unreliable (high variance).

$$d_k = \mathrm{sign}(y_k - n_k \hat{\pi}_k) \left\{ \sqrt{2[\ell_{\mathrm{full}}(x_k) - \ell(\hat{\beta}; x_k)]} \right\}$$

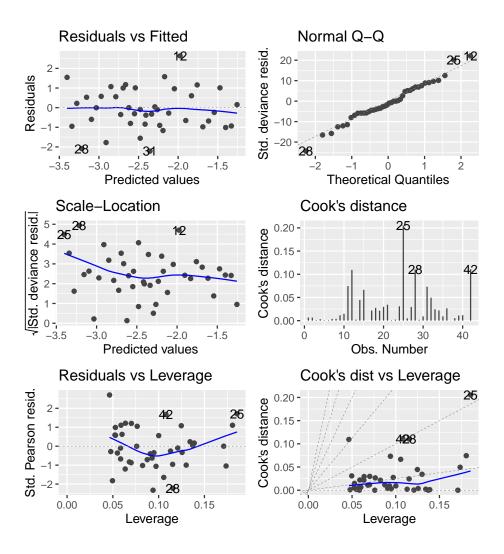

0.20.5.1 Standardized deviance residuals

$$r_{D_k} = \frac{d_k}{\sqrt{1-h_k}}$$

0.20.6 Diagnostic plots

Let's take a look at the full set of autoplot() diagnostics now for our CHD model:

```
chd_glm_strat_grouped |> autoplot(which = 1:6) |> print()
```

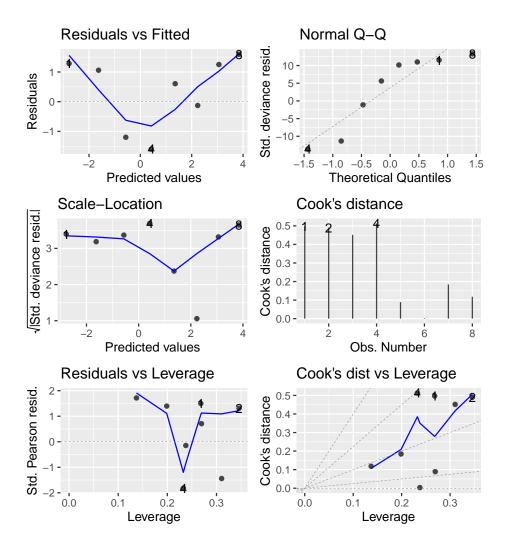

Things look pretty good here. The QQ plot is still usable; with large samples; the residuals should be approximately Gaussian.

0.20.6.1 Beetles

Let's look at the beetles model diagnostic plots for comparison:

```
beetles_glm_grouped |> autoplot(which = 1:6) |> print()
```

Hard to tell much from so little data, but there might be some issues here.

0.21 Odds Ratios vs Probability (Risk) Ratios

Definition 0.11 (Relative risk). The **relative risk** comparing two probabilities π_1 and π_2 , also known as the **risk ratio**, **relative risk ratio**, **probability ratio**, and **rate ratio**, is:

$$\rho(1,2) \stackrel{\mathrm{def}}{=} \frac{\pi_1}{\pi_2}$$

0.21.0.1 Case 1: rare events

For rare events, odds ratios and probability (a.k.a. risk, a.k.a. prevalence) ratios will be close:

```
\pi_1 = .01 \ \pi_2 = .02 
pi1 = .01 
pi2 = .02 
pi2/pi1
```

[1] 2

```
odds(pi2)/odds(pi1)
```

[1] 2.0204082

0.21.0.2 Case 2: frequent events

$$\pi_1 = .4 \ \pi_2 = .5$$

For more frequently-occurring outcomes, this won't be the case:

```
pi1 = .4
pi2 = .5
pi2/pi1

[1] 1.25

odds(pi2)/odds(pi1)
```

[1] 1.5

If you want risk ratios, you can sometimes get them by changing the link function:

```
data(anthers, package = "dobson")
anthers.sum<-aggregate(
  anthers[c("n","y")],
  by=anthers[c("storage")],FUN=sum)

anthers_glm_log = glm(
  formula = cbind(y,n-y)~storage,
  data=anthers.sum,
  family=binomial(link="log"))

anthers_glm_log |> parameters() |> print_md()
```

Parameter	Log-Risk	SE	95% CI	Z	p
(Intercept)	-0.80	0.12	(-1.04, -0.58)	-6.81	< .001
storage	0.17	0.07	(0.02, 0.31)	2.31	0.021

Now $\exp \{\beta\}$ gives us risk ratios instead of odds ratios:

anthers_glm_log |> parameters(exponentiate = TRUE) |> print_md()

Parameter	Risk Ratio	SE	95% CI	Z	p
(Intercept) storage	0.45 1.18		(0.35, 0.56) (1.03, 1.36)		

Let's compare this model with a logistic model:

```
anthers_glm_logit = glm(
  cbind(y,n-y)~storage,
  data=anthers.sum,
  family=binomial(link="logit"))

anthers_glm_logit |> parameters(exponentiate = TRUE) |> print_md()
```

Parameter	Odds Ratio	SE	95% CI	Z	p
(Intercept) storage	0.76 1.49		(0.45, 1.27) (1.06, 2.10)		

[to add: fitted plots on each outcome scale]

When I try to use link ="log" in practice, I often get errors about not finding good starting values for the estimation procedure. This is likely because the model is producing fitted probabilities greater than 1.

When this happens, you can try to fit Poisson regression models instead (we will see those soon!). But then the outcome distribution isn't quite right, and you won't get warnings about fitted probabilities greater than 1. In my opinion, the Poisson model for binary outcomes is confusing and not very appealing.

0.22 Models for Count Outcomes

(Poisson Regression and Variations)

Configuring R

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
library(ggeasy) # help with graphics
library(dplyr) # manipulate data
library(haven) # import Stata files
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
options('digits' = 4)
```

0.23 Introduction

0.23.1 Examples of count outcomes

- Cyclones per season
- Seconds of tooth-brushing per session (if rounded)
- Infections per person-year
- Visits to ER per person-month
- Car accidents per 1000 miles driven

Note

In many count outcomes, there is some sense of "exposure magnitude" or "duration of observation": person-year, time at risk, session, miles driven, etc.

0.23.2 Poisson distribution

$$P(Y=y) = \frac{\mu^y e^{-\mu}}{y!}$$

0.23.2.1 Properties

- $\mathbb{E}[Y] = \mu$
- $Var[Y] = \mu$

0.23.3 Accounting for exposure

If the exposures/observation durations, denoted T=t, are not all equal, we model

$$\mu = \lambda t$$

 λ is interpreted as the "expected event rate per unit of exposure"; that is,

$$\lambda = \frac{\mathbb{E}[Y|T=t]}{t}$$

! Important

The exposure magnitude, T, is *similar* to a covariate in linear or logistic regression. However, there is an important difference: in count regression, **there is no intercept corresponding to** $\mathbb{E}[Y|T=0]$. In other words, this model assumes that if there is no exposure, there can't be any events.

0.23.4 Adding covariates

With covariates, λ becomes a function of the covariates $\tilde{X} = (X_1, \dots, X_n)$, with a log $\{\}$ link function (and thus an $\exp\{\}$ inverse-link). That is:

$$\begin{split} \mathbb{E}[Y|\tilde{X} = \tilde{x}, T = t] &= \mu(\tilde{x}, t) \\ \mu(\tilde{x}, t) &= \lambda(\tilde{x}) \cdot t \\ \lambda(\tilde{x}) &= \exp\left\{\eta(\tilde{x})\right\} \\ \eta(\tilde{x}) &= \tilde{x}'\tilde{\beta} = \beta_0 + \beta_1 x_1 + \dots + \beta_n x_n \end{split}$$

Therefore,

$$\begin{split} \log\left\{\{\mathbb{E}[Y|\tilde{X}=\tilde{x},T=t]\}\right\} &= \log\left\{\{\mu(\tilde{x})\}\right\} \\ &= \log\left\{\{\lambda(\tilde{x})\cdot t\}\right\} \\ &= \log\left\{\lambda(\tilde{x})\right\} + \log\left\{t\right\} \\ &= \log\left\{\exp\left\{\eta(\tilde{x})\right\}\right\} + \log\left\{t\right\} \\ &= \eta(\tilde{x}) + \log\left\{t\right\} \\ &= \tilde{x}'\tilde{\beta} + \log\left\{t\right\} \\ &= (\beta_0 + \beta_1 x_1 + \dots + \beta_p x_p) + \log\left\{t\right\} \end{split}$$

In contrast with the Xs, T enters this expression with a $\log \{\}$ transformation and without a corresponding β coefficient.

Note

Terms that enter the linear component of a model without a coefficient, such as $\log \{t\}$ here, are called **offsets**.

0.23.5 Rate ratios

Differences on the log-rate scale become ratios on the rate scale.

? Tip

$$\exp\left\{a - b\right\} = \frac{\exp\left\{a\right\}}{\exp\left\{b\right\}}$$

Therefore, according to this model, differences of δ in covariate x_j correspond to rate ratios of $\exp\{\beta_j \cdot \delta\}$.

That is, letting \tilde{X}_{-j} denote vector \tilde{X} with element j removed:

$$\begin{split} &\left\{ \begin{array}{l} \log \left\{ \mathbb{E}[Y|\boldsymbol{X}_{j}=\boldsymbol{a},\tilde{\boldsymbol{X}}_{-j}=\tilde{\boldsymbol{x}}_{-j},T=t] \right\} \\ -\log \left\{ \mathbb{E}[Y|\boldsymbol{X}_{j}=\boldsymbol{b},\tilde{\boldsymbol{X}}_{-j}=\tilde{\boldsymbol{x}}_{-j},T=t] \right\} \end{array} \right\} \\ &= \left\{ \begin{array}{l} \log \left\{ t \right\} + \beta_{0} + \beta_{1}x_{1} + \ldots + \beta_{j}(\boldsymbol{a}) + \ldots + \beta_{p}x_{p} \\ -\log \left\{ t \right\} + \beta_{0} + \beta_{1}x_{1} + \ldots + \beta_{j}(\boldsymbol{b}) + \ldots + \beta_{p}x_{p} \end{array} \right\} \\ &= \beta_{j}(\boldsymbol{a}-\boldsymbol{b}) \end{split}$$

And accordingly,

$$\frac{\mathbb{E}[Y|\boldsymbol{X_j}=a,\tilde{X}_{-j}=\tilde{x}_{-j},T=t]}{\mathbb{E}[Y|\boldsymbol{X_j}=b,\tilde{X}_{-j}=\tilde{x}_{-j},T=t]}=\exp\left\{\beta_j(a-b)\right\}$$

0.24 Inference for count regression models

0.24.1 Confidence intervals for regression coefficients and rate ratios

As usual:

$$\beta \in \left[\hat{\beta} \pm z_{1 - \frac{\alpha}{2}} \cdot \hat{\operatorname{se}} \left(\hat{\beta} \right) \right]$$

Rate ratios: exponentiate CI endpoints

$$\exp\left\{\beta\right\} \in \left[\exp\left\{\hat{\beta} \pm z_{1-\frac{\alpha}{2}} \cdot \hat{\operatorname{se}}\left(\hat{\beta}\right)\right\}\right]$$

0.24.2 Hypothesis tests for regression coefficients

$$t = \frac{\hat{\beta} - \beta_0}{\hat{\operatorname{se}}\left(\hat{\beta}\right)}$$

Compare t or |t| to the tails of the standard Gaussian distribution, according to the null hypothesis.

0.24.3 Comparing nested models

log(likelihood ratio) tests, as usual.

0.25 Prediction

$$\begin{split} \hat{y} &\stackrel{\text{def}}{=} \hat{\mathbb{E}}[Y|\tilde{X} = \tilde{x}, T = t] \\ &= \hat{\mu}(\tilde{x}, t) \\ &= \hat{\lambda}(\tilde{x}) \cdot t \\ &= \exp\left\{\hat{\eta}(\tilde{x})\right\} \cdot t \\ &= \exp\left\{\tilde{x}'\hat{\beta}\right\} \cdot t \end{split}$$

0.26 Diagnostics

0.26.1 Residuals

0.26.1.1 Observation residuals

$$e \stackrel{\mathrm{def}}{=} y - \hat{y}$$

0.26.1.2 Pearson residuals

$$r = \frac{e}{\hat{\operatorname{se}}\left(e\right)} \approx \frac{e}{\sqrt{\hat{y}}}$$

0.26.1.3 Standardized Pearson residuals

$$r_p = \frac{r}{\sqrt{1-h}}$$

where h is the "leverage" (which we will continue to leave undefined).

0.26.1.4 Deviance residuals

$$d_k = \mathrm{sign}(y - \hat{y}) \left\{ \sqrt{2[\ell_{\mathrm{full}}(y) - \ell(\hat{\beta}; y)]} \right\}$$

Note

$$\operatorname{sign}(x) \stackrel{\text{def}}{=} \frac{x}{|x|}$$

In other words:

- $\begin{array}{ll} \bullet & \mathrm{sign}(x) = -1 \ \mathrm{if} \ x < 0 \\ \bullet & \mathrm{sign}(x) = 0 \ \mathrm{if} \ x = 0 \end{array}$
- $\operatorname{sign}(x) = 1 \text{ if } x > 0$

0.27 Zero-inflation

0.27.1 Models for zero-inflated counts

We assume a latent (unobserved) binary variable, Z, which we model using logistic regression:

$$P(Z = 1|X = x) = \pi(x) = \text{expit}(\gamma_0 + \gamma_1 x_1 + ...)$$

According to this model, if Z = 1, then Y will always be zero, regardless of X and T:

$$P(Y = 0|Z = 1, X = x, T = t) = 1$$

Otherwise (if Z = 0), Y will have a Poisson distribution, conditional on X and T, as above.

Even though we never observe Z, we can estimate the parameters γ_0 - γ_p , via maximum likelihood:

$$P(Y = y|X = x, T = t) = P(Y = y, Z = 1|...) + P(Y = y, Z = 0|...)$$

(by the Law of Total Probability)

where

$$P(Y = y, Z = z | ...) = P(Y = y | Z = z, ...) P(Z = z | ...)$$

0.27.1.1 Exercise

Expand P(Y = 0|X = x, T = t), P(Y = 1|X = x, T = t) and P(Y = y|X = x, T = t) into expressions involving P(Z = 1|X = x, T = t) and P(Y = y|Z = 0, X = x, T = t).

0.27.1.2 Exercise

Derive the expected value and variance of Y, conditional on X and T, as functions of P(Z=1|X=x,T=t) and $\mathbb{E}[Y|Z=0,X=x,T=t]$.

0.28 Over-dispersion

0.28.1 Negative binomial models

The Poisson distribution model **forces** the variance to equal the mean. In practice, many count distributions will have a variance substantially larger than the mean (or occasionally smaller).

When we encounter this, we can try to reduce the residual variance by adding more covariates. However, there are also alternatives to the Poisson model.

Most notably, the negative binomial model:

$$P(Y = y) = \frac{\mu^y}{y!} \cdot \frac{\Gamma(\rho + y)}{\Gamma(\rho) \cdot (\rho + \mu)^y} \cdot \left(1 + \frac{\mu}{\rho}\right)^{-\rho}$$

where ρ is an overdispersion parameter and $\Gamma(x)=(x-1)!$ for integers x.

You don't need to memorize or understand this expression, but as $\rho \to \infty$, the second term converges to 1 and the third term converges to $\{-\mu\}$, which brings us back to the Poisson distribution.

For this distribution, $\mathbb{E}[Y] = \mu$ and $\operatorname{Var}(Y) = \mu + \frac{\mu^2}{\rho} > \mu$.

We can still model μ as a function of X and T as before, and we can combine this model with zero-inflation by using it in place of the Poisson distribution for P(Y=y|Z=0,X=x,T=t).

0.28.2 Quasipoisson

An alternative to Negative binomial is the "quasipoisson" distribution. I've never used it, but it seems to be a method-of-moments type approach rather than maximum likelihood. It models the variance as $Var(Y) = \mu\theta$, and estimates θ accordingly.

See ?quasipoisson in R for more.

Time to Event Models

This section is adapted starting from the lecture notes by David Rocke from the 2021 edition of Epi 204:

http://dmrocke.ucdavis.edu/Class/EPI204-Spring-2021/EPI204-Spring-2021.html

0.29 Introduction to Survival Analysis

Configuring R

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
library(ggeasy) # help with graphics
library(scales) # scales formatting
library(dplyr) # manipulate data
library(haven) # import Stata files
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
```

Time to Event Models

```
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
pander::panderOptions("table.split.table", Inf)
conflicts_prefer(dplyr::filter) # use the `filter()` function from dplyr() by defa
options('digits' = 4)
```

0.30 Time-to-event outcome distributions

0.30.1 Time to Event Data

- Survival Analysis is a term for analyzing time-to-event data.
- This is used in clinical trials, where the event is often death or recurrence of disease.
- It is used in engineering reliability analysis, where the event is failure of a device or system.
- It is used in insurance, particularly life insurance, where the event is death.

0.30.2 Distributions of Time-to-Event Data

- The distribution of event times is asymmetric and can be long-tailed, and starts at 0 (that is, P(T < 0) = 0).
- The base distribution is not normal, but exponential.

- There are usually **censored** observations, which are ones in which the failure time is not observed.
- Often, these are **right-censored**, meaning that we know that the event occurred after some known time t, but we don't know the actual event time, as when a patient is still alive at the end of the study.
- Observations can also be **left-censored**, meaning we know the event has already happened at time t, or **interval-censored**, meaning that we only know that the event happened between times t_1 and t_2 .
- Analysis is difficult if censoring is associated with treatment.

0.30.3 Right Censoring

- Patients are in a clinical trial for cancer, some on a new treatment and some on standard of care.
- Some patients in each group have died by the end of the study. We know the survival time (measured for example from time of diagnosis—each person on their own clock).
- Patients still alive at the end of the study are right censored.
- Patients who are lost to follow-up or withdraw from the study may be right-censored.

0.30.4 Left and Interval Censoring

- An individual tests positive for HIV.
- If the event is infection with HIV, then we only know that it has occurred before the testing time t, so this is left censored.
- If an individual has a negative HIV test at time t_1 and a positive HIV test at time t_2 , then the infection event is interval censored.

0.30.5 Distribution functions for time-to-event variables

0.30.5.1 The Probability Density Function (PDF)

For a time-to-event variable T with a continuous distribution, the **probability density function** is defined as usual:

$$f(t) \stackrel{\text{def}}{=} p(t) \stackrel{\text{def}}{=} p(T=t)$$

Typically, this density is assumed to be 0 for all t < 0; that is, $f(t) = 0, \forall t < 0$. In other words, the range of T is typically $[0, \infty)$.

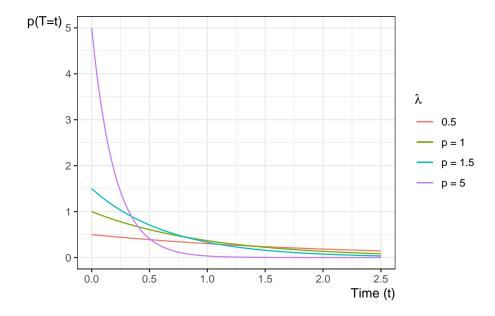

Example: exponential distribution

Recall from Epi 202: the pdf of the exponential distribution family of models is:

$$p(T=t) = \mathbb{1}_{t \geq 0} \cdot \lambda \mathrm{e}^{-\lambda t}$$

where $\lambda > 0$.

Here are some examples of exponential pdfs:

0.30.5.2 The Cumulative Distribution Function (CDF)

The **cumulative distribution function** is defined as:

$$F(t) \stackrel{\text{def}}{=} \Pr(T \le t)$$
$$= \int_{u=0}^{t} f(u) du$$

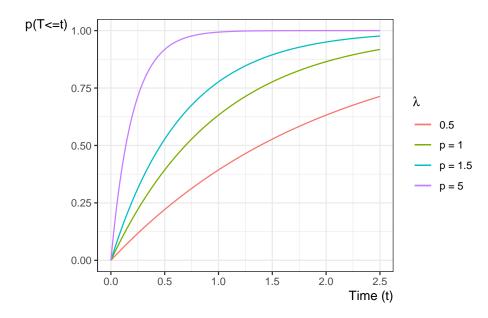

Example: exponential distribution

Recall from Epi 202: the cdf of the exponential distribution family of models is:

$$P(T \leq t) = \mathbb{1}_{t \geq 0} \cdot (1 - \mathrm{e}^{-\lambda t})$$

where $\lambda > 0$.

Here are some examples of exponential cdfs:

0.30.5.3 The Survival Function

For survival data, a more important quantity is the **survival function**:

$$S(t) \stackrel{\text{def}}{=} \Pr(T > t)$$
$$= \int_{u=t}^{\infty} p(u) du$$
$$= 1 - F(t)$$

The survival function S(t) is the probability that the event time is later than t. If the event in a clinical trial is death, then this is the expected

fraction of the original population at time 0 that is still alive at time t; that is, the fraction surviving to time t.

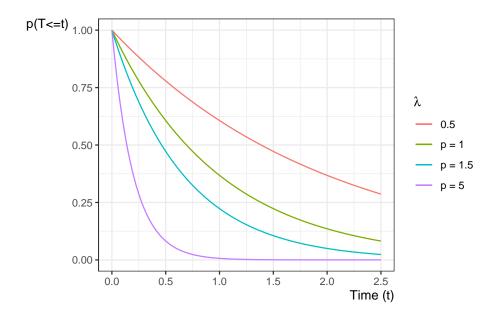

Example: exponential distribution

Since S(t) = 1 - F(t), the survival function of the exponential distribution family of models is:

$$P(T > t) = \mathbb{1}_{t > 0} \cdot e^{-\lambda t}$$

where $\lambda > 0$.

Here are some examples of exponential pdfs:

0.30.5.4 The Hazard Function

Another important quantity is the **hazard function**, which represents the probability that the event will occur at time t, given that it has not occurred yet:

$$h(t) \stackrel{\text{def}}{=} p(T = t | T \ge t)$$

Note

Recall from Epi 202: if $A \subseteq B$ then $p(A \cap B) = p(A)$.

Now, $\{T=t\}\subseteq \{T\geq t\}$. So:

$$p(T=t, T \ge t) = p(T=t \cap T \ge t)$$
$$= p(T=t)$$

Hence:

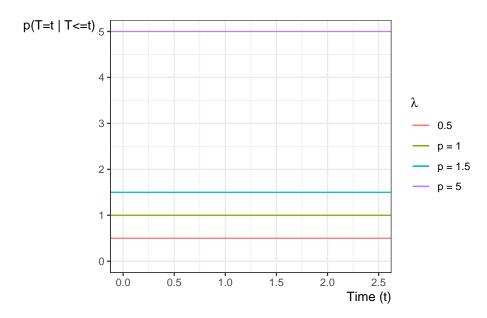

$$\begin{split} h(t) &= p(T=t|T \geq t) \\ &= \frac{p(T=t,T \geq t)}{p(T \geq t)} \\ &= \frac{p(T=t)}{p(T \geq t)} \\ &= \frac{f(t)}{S(t)} \end{split}$$

Example: exponential distribution

The hazard function of the exponential distribution family of models is:

$$P(T>t)=\mathbb{1}_{t>0}\cdot\lambda$$

Here are some examples of exponential hazard functions:

0.30.5.5 The Cumulative Hazard Function

The **cumulative hazard function** H(t) is defined as:

$$H(t) \stackrel{\mathrm{def}}{=} \int_{u=0}^{t} h(u) du$$

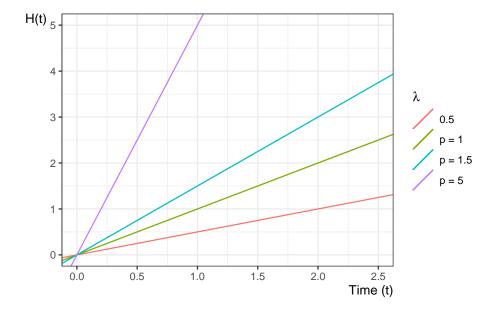

As we will see below, H(t) is tractable to estimate, and we can then derive an estimate the hazard function using an approximate derivative of the estimated cumulative hazard.

Example: exponential distribution

The cumulative hazard function of the exponential distribution family of models is:

$$H(t) = \mathbb{1}_{t \geq 0} \cdot \lambda t$$

Here are some examples of exponential cumulative hazard functions:

0.30.5.6 Some Key Mathematical Relationships among Survival Concepts

$$\begin{split} S(t) &= 1 - F(t) \\ &= \exp\left\{-H(t)\right\} \\ S'(t) &= -f(t) \\ H(t) &= -\log\left\{S(t)\right\} \\ H'(t) &= h(t) \\ h(t) &= \frac{f(t)}{S(t)} \\ f(t) &= h(t) \cdot S(t) \end{split}$$

Some proofs (others left as exercises):

$$S'(t) = \frac{d}{dt}(1 - F(t))$$
$$= -F'(t)$$
$$= -f(t)$$

$$\begin{split} \frac{d}{dt} \mathrm{log} \left\{ S(t) \right\} &= \frac{S'(t)}{S(t)} \\ &= -\frac{f(t)}{S(t)} \\ &= -h(t) \end{split}$$

$$\begin{split} H(t) &\stackrel{\text{def}}{=} \int_{u=0}^{t} h(u) du \\ &= \int_{0}^{t} -\frac{d}{du} \log \left\{ S(u) \right\} du \\ &= \left[-\log \left\{ S(u) \right\} \right]_{u=0}^{u=t} \\ &= \left[\log \left\{ S(u) \right\} \right]_{u=t}^{u=0} \\ &= \log \left\{ S(0) \right\} - \log \left\{ S(t) \right\} \\ &= \log \left\{ 1 \right\} - \log \left\{ S(t) \right\} \\ &= -\log \left\{ S(t) \right\} \end{split}$$

Equivalently:

$$S(t) = \exp\left\{-H(t)\right\}$$

0.30.5.7 Example: Time to death the US in 2004

Daily hazard rates for US Females in 2004

The first day is the most dangerous:

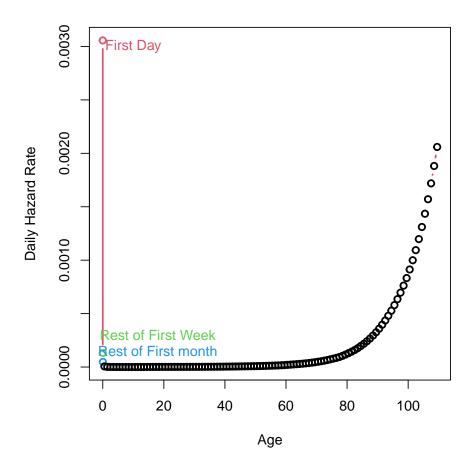

Figure 13: Daily Hazard Rates in 2004 for US Females

Daily hazard rates for US Males and Females in 2004

Exercise: hypothesize why these curves differ where they do?

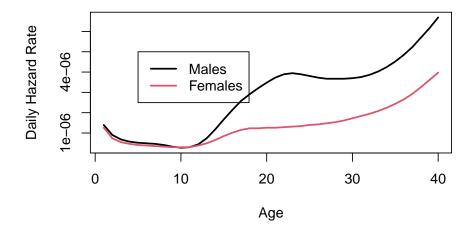

Figure 14: Daily Hazard Rates in 2004 for US Males and Females 1-40 $\,$

Survival curve for US females

Exercise: compare and contrast this curve with the corresponding hazard curve.

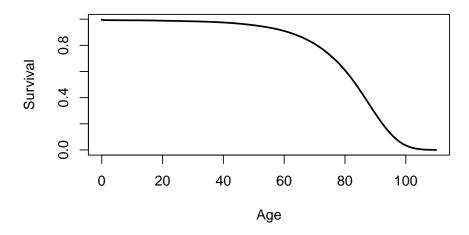

Figure 15: Survival Curve in 2004 for US Females

0.30.5.8 Likelihood with censoring *

Note

This subsection was not presented in class in 2023; it is not necessary to understand for the qualifying exam.

If an event time T is observed exactly as T=t, then the likelihood of that observation is just its probability density function:

$$\begin{split} \mathcal{L}(t) &= p(T=t) \\ &\stackrel{\text{def}}{=} f_T(t) \\ &= h_T(t) S_T(t) \\ \ell(t) &\stackrel{\text{def}}{=} \log \left\{ \mathcal{L}(t) \right\} \\ &= \log \left\{ h_T(t) S_T(t) \right\} \\ &= \log \left\{ h_T(t) \right\} + \log \left\{ S_T(t) \right\} \\ &= \log \left\{ h_T(t) \right\} - H_T(t) \end{split}$$

If instead the event time T is censored and only known to be after time y, then the likelihood of that censored observation is instead the survival function evaluated at the censoring time:

$$\begin{split} \mathcal{L}(y) &= p_T(T > y) \\ &\stackrel{\text{def}}{=} S_T(y) \\ \ell(y) &\stackrel{\text{def}}{=} \log \left\{ \mathcal{L}(y) \right\} \\ &= \log \left\{ S(y) \right\} \\ &= -H(y) \end{split}$$

What's written above is incomplete. We also observed whether or not the observation was censored. Let C denote the time when censoring would occur (if the event did not occur first); let $f_C(y)$ and $S_C(y)$ be the corresponding density and survival functions for the censoring event.

Let Y denote the time when observation ended (either by censoring or by the event of interest occurring), and let D be an indicator variable for the event occurring at Y (so D=0 represents a censored observation and D=1 represents an uncensored observation). In other words, let $Y \stackrel{\text{def}}{=} \min(T,C)$ and $D \stackrel{\text{def}}{=} \mathbb{1}\{T \le C\}$.

Then the complete likelihood of the observed data (Y, D) is:

$$\begin{split} \mathcal{L}(y,d) &= p(Y=y,D=d) \\ &= \left[p(T=y,C>y) \right]^d \cdot \left[p(T>y,C=y) \right]^{1-d} \end{split}$$

Typically, survival analyses assume that C and T are mutually independent; this assumption is called "non-informative" censoring.

Then the joint likelihood p(Y,D) factors into the product p(Y),p(D), and the likelihood reduces to:

$$\begin{split} \mathcal{L}(y,d) &= \left[p(T=y,C>y) \right]^d \cdot \left[p(T>y,C=y) \right]^{1-d} \\ &= \left[p(T=y)p(C>y) \right]^d \cdot \left[p(T>y)p(C=y) \right]^{1-d} \\ &= \left[f_T(y)S_C(y) \right]^d \cdot \left[S(y)f_C(y) \right]^{1-d} \\ &= \left[f_T(y)^d S_C(y)^d \right] \cdot \left[S_T(y)^{1-d} f_C(y)^{1-d} \right] \\ &= (f_T(y)^d \cdot S_T(y)^{1-d}) \cdot (f_C(y)^{1-d} \cdot S_C(y)^d) \end{split}$$

The corresponding log-likelihood is:

$$\begin{split} \ell(y,d) &= \log \left\{ \mathcal{L}(y,d) \right\} \\ &= \log \left\{ \left(f_T(y)^d \cdot S_T(y)^{1-d} \right) \cdot \left(f_C(y)^{1-d} \cdot S_C(y)^d \right) \right\} \\ &= \log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} + \log \left\{ f_C(y)^{1-d} \cdot S_C(y)^d \right\} \end{split}$$

Let

- θ_T represent the parameters of $p_T(t)$,
- θ_C represent the parameters of $p_C(c)$,
- $\theta = (\theta_T, \theta_C)$ be the combined vector of all parameters.

Then corresponding score function is:

$$\begin{split} \ell'(y,d) &= \frac{d}{d\theta} \left[\log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} + \log \left\{ f_C(y)^{1-d} \cdot S_C(y)^d \right\} \right] \\ &= \left(\frac{d}{d\theta} \log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} \right) + \left(\frac{d}{d\theta} \log \left\{ f_C(y)^{1-d} \cdot S_C(y)^d \right\} \right) \end{split}$$

As long as θ_C and θ_T don't share any parameters, then if censoring is non-informative, the partial derivative with respect to θ_T is:

$$\begin{split} \ell_{\theta_T}'(y,d) &\stackrel{\text{def}}{=} \frac{d}{d\theta_T} \ell(y,d) \\ &= \left(\frac{d}{d\theta_T} \log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} \right) + \left(\frac{d}{d\theta_T} \log \left\{ f_C(y)^{1-d} \cdot S_C(y)^d \right\} \right) \\ &= \left(\frac{d}{d\theta_T} \log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} \right) + 0 \\ &= \frac{d}{d\theta_T} \log \left\{ f_T(y)^d \cdot S_T(y)^{1-d} \right\} \end{split}$$

Thus, the MLE for θ_T won't depend on θ_C , and we can ignore the distribution of C when estimating the parameters of $f_T(t) = p(T=t)$.

Then:

$$\begin{split} \mathcal{L}(y,d) &= f_T(y)^d \cdot S_T(y)^{1-d} \\ &= (h_T(y)^d S_T(y)^d) \cdot S_T(y)^{1-d} \\ &= h_T(y)^d \cdot S_T(y)^d \cdot S_T(y)^{1-d} \\ &= h_T(y)^d \cdot S_T(y) \\ &= S_T(y) \cdot h_T(y)^d \end{split}$$

That is, if the event occurred at time y (i.e., if d = 1), then the likelihood of (Y, D) = (y, d) is equal to the hazard function at y times the survival

function at y. Otherwise, the likelihood is equal to just the survival function at y.

The corresponding log-likelihood is:

$$\begin{split} \ell(y,d) &= \log \left\{ \mathcal{L}(y,d) \right\} \\ &= \log \left\{ S_T(y) \cdot h_T(y)^d \right\} \\ &= \log \left\{ S_T(y) \right\} + \log \left\{ h_T(y)^d \right\} \\ &= \log \left\{ S_T(y) \right\} + d \cdot \log \left\{ h_T(y) \right\} \\ &= -H_T(y) + d \cdot \log \left\{ h_T(y) \right\} \end{split}$$

In other words, the log-likelihood contribution from a single observation (Y, D) = (y, d) is equal to the negative cumulative hazard at y, plus the log of the hazard at y if the event occurred at time y.

Note

End of extra section.

0.31 Parametric Models for Time-to-Event Outcomes

0.31.1 Exponential Distribution

- The exponential distribution is the base distribution for survival analysis.
- The distribution has a constant hazard λ
- The mean survival time is λ^{-1}

0.31.1.1 Mathematical details of exponential distribution

$$\begin{split} f(t) &= \lambda \mathrm{e}^{-\lambda t} \\ E(t) &= \lambda^{-1} \\ Var(t) &= \lambda^{-2} \\ F(t) &= 1 - \mathrm{e}^{-\lambda x} \\ S(t) &= \mathrm{e}^{-\lambda x} \\ \ln(S(t)) &= -\lambda x \\ h(t) &= -\frac{f(t)}{S(t)} = -\frac{\lambda \mathrm{e}^{-\lambda t}}{\mathrm{e}^{-\lambda t}} = \lambda \end{split}$$

0.31.1.2 Estimation of λ

- Suppose we have m exponential survival times of t_1, t_2, \ldots, t_m and k right-censored values at u_1, u_2, \ldots, u_k .
- A survival time of $t_i = 10$ means that subject i died at time 10. A right-censored time $u_i = 10$ means that at time 10, subject i was still alive and that we have no further follow-up.
- For the moment we will assume that the survival distribution is exponential and that all the subjects have the same parameter λ .

We have m exponential survival times of t_1,t_2,\ldots,t_m and k right-censored values at u_1,u_2,\ldots,u_k . The log-likelihood of an observed survival time t_i is

$$\log\left\{\lambda\mathrm{e}^{-\lambda t_i}\right\} = \log\left\{\lambda\right\} - \lambda t_i$$

and the likelihood of a censored value is the probability of that outcome (survival greater than u_i) so the log-likelihood is

$$\log\left\{\lambda \mathbf{e}^{u_j}\right\} = -\lambda u_j.$$

Let
$$T = \sum t_i$$
 and $U = \sum u_i$. Then:

$$\begin{split} \ell(\lambda) &= \sum_{i=1}^m (\ln \lambda - \lambda t_i) + \sum_{j=1}^k (-\lambda u_j) \\ &= m \ln \lambda - (T+U) \lambda \\ \ell'(\lambda) &= m \lambda^{-1} - (T+U) \\ \hat{\lambda} &= \frac{m}{T+U} \\ \ell'' &= -m/\lambda^2 \\ &< 0 \\ \hat{E}[T] &= \hat{\lambda}^{-1} \\ &= \frac{T+U}{m} \end{split}$$

0.31.1.3 Fisher Information and Standard Error

$$\begin{split} E[-\ell''] &= m/\lambda^2 \\ \operatorname{Var}\left(\hat{\lambda}\right) &\approx \left(E[-\ell'']\right)^{-1} \\ &= \lambda^2/m \\ \operatorname{SE}\left(\hat{\lambda}\right) &= \sqrt{\operatorname{Var}\left(\hat{\lambda}\right)} \\ &\approx \lambda/\sqrt{m} \end{split}$$

 $\hat{\lambda}$ depends on the censoring times of the censored observations, but $\text{Var}(\hat{\lambda})$ only depends on the number of uncensored observations, m, and not on the number of censored observations (k).

0.31.1.4 Other Parametric Survival Distributions

• Any density on $[0, \infty)$ can be a survival distribution, but the most useful ones are all skew right.

- The commonest generalization of the exponential is the Weibull.
- Other common choices are the gamma, log-normal, log-logistic, Gompertz, inverse Gaussian, and Pareto.
- Most of what we do going forward is non-parametric or semiparametric, but sometimes these parametric distributions provide a useful approach.

0.31.2 Weibull Distribution

$$\begin{split} p(t) &= \alpha \lambda x^{\alpha-1} \mathrm{e}^{-\lambda x^{\alpha}} \\ h(t) &= \alpha \lambda x^{\alpha-1} \\ S(t) &= \mathrm{e}^{-\lambda x^{\alpha}} \\ E(T) &= \Gamma(1+1/\alpha) \cdot \lambda^{-1/\alpha} \end{split}$$

When $\alpha=1$ this is the exponential. When $\alpha>1$ the hazard is increasing and when $\alpha<1$ the hazard is decreasing. This provides more flexibility than the exponential.

We will see more of this distribution later.

0.32 Nonparametric Survival Analysis

0.32.1 Basic ideas

- Mostly, we work without a parametric model.
- The first task is to estimate a survival function from data listing survival times, and censoring times for censored data.
- For example one patient may have relapsed at 10 months. Another might have been followed for 32 months without a relapse having occurred (censored).

• The minimum information we need for each patient is a time and a censoring variable which is 1 if the event occurred at the indicated time and 0 if this is a censoring time.

0.33 Example: clinical trial for pediatric acute leukemia

0.33.1 Overview of study

This is from a clinical trial in 1963 for 6-MP treatment vs. placebo for Acute Leukemia in 42 children.

- Pairs of children:
 - matched by remission status at the time of treatment (remstat:
 1 = partial, 2 = complete)
 - randomized to 6-MP (exit times in t2) or placebo (exit times in t1)
- Followed until relapse or end of study.
- All of the placebo group relapsed, but some of the 6-MP group were censored (which means they were still in remission); indicated by relapse variable (0 = censored, 1 = relapse).
- 6-MP = 6-Mercaptopurine (Purinethol) is an anti-cancer ("antineoplastic" or "cytotoxic") chemotherapy drug used currently for Acute lymphoblastic leukemia (ALL). It is classified as an antimetabolite.

0.33.2 Study design

Clinical trial in 1963 for 6-MP treatment vs. placebo for Acute Leukemia in 42 children. Pairs of children matched by remission status at the time of treatment (1 = partial or 2 = complete) and randomized to 6-MP or placebo. Followed until relapse or end of study. All of the placebo group relapsed, but some of the 6-MP group were censored.

```
library(printr) # inserts help-file output into markdown output
library(KMsurv)
?drug6mp

data from Section 1.2

Description:

The 'drug6mp' data frame has 21 rows and 5 columns.

Format:

This data frame contains the following columns:

pair pair number

remstat Remission status at randomization (1=partial, 2=complete)

t1 Time to relapse for placebo patients, months

t2 Time to relapse for 6-MP patients, months

relapse Relapse indicator (0=censored, 1=relapse) for 6-MP patients
```

0.33.4 Descriptive Statistics

• The average time in each group is not useful. Some of the 6-MP patients have not relapsed at the time recorded, while all of the placebo patients have relapsed.

- The median time is not really useful either because so many of the 6-MP patients have not relapsed (12/21).
- Both are biased down in the 6-MP group. Remember that lower times are worse since they indicate sooner recurrence.
- We can compute the average hazard rate, which is the estimate of the exponential parameter: number of relapses divided by the sum of the times.
- For the placebo, that is just the reciprocal of the mean time = 1/8.667 = 0.115.
- For the 6-MP group this is 9/359 = 0.025
- The estimated average hazard in the placebo group is 4.6 times as large (if the hazard is constant over time).

0.34 The Kaplan-Meier Product Limit Estimator

- The estimated survival function for the placebo patients is easy to compute. For any time t in months, S(t) is the fraction of patients with times greater than t.
- For the 6-MP patients, we cannot ignore the censored data because we know that the time to relapse is greater than the censoring time.
- For any time t in months, we know that 6-MP patients with times greater than t have not relapsed, and those with relapse time less than t have relapsed, but we don't know if patients with censored time less than t have relapsed or not.
- The procedure we usually use is the Kaplan-Meier product-limit estimator of the survival function.
- The Kaplan-Meier estimator is a step function (like the empirical cdf), which changes value only at the event times, not at the censoring times.

- At each event time t, we compute the at-risk group size Y, which is all those observations whose event time or censoring time is at least t.
- If d of the observations have an event time (not a censoring time) of t, then the group of survivors immediately following time t is reduced by the fraction

$$\frac{Y-d}{Y} = 1 - \frac{d}{Y}$$

If the event times are t_i with events per time of d_i $(1 \le i \le k)$, then

$$\hat{S}(t) = \prod_{t_i < t} [1 - d_i/Y_i]$$

where Y_i is the set of observations whose time (event or censored) is $\geq t_i$, the group at risk at time t_i .

If there are no censored data, and there are n data points, then just after (say) the third event time

$$\begin{split} \hat{S}(t) &= \prod_{t_i < t} [1 - d_i / Y_i] \\ &= [\frac{n - d_1}{n}] [\frac{n - d_1 - d_2}{n - d_1}] [\frac{n - d_1 - d_2 - d_3}{n - d_1 - d_2}] \\ &= \frac{n - d_1 - d_2 - d_3}{n} \\ &= 1 - \frac{d_1 + d_2 + d_3}{n} \\ &= 1 - \hat{F}(t) \end{split}$$

where $\hat{F}(t)$ is the usual empirical CDF estimate.

0.34.1 Kaplan-Meier curve for drug6mp data

Here is the Kaplan-Meier estimated survival curve for the patients who received 6-MP in the drug6mp dataset (we will see code to produce figures like this one shortly):

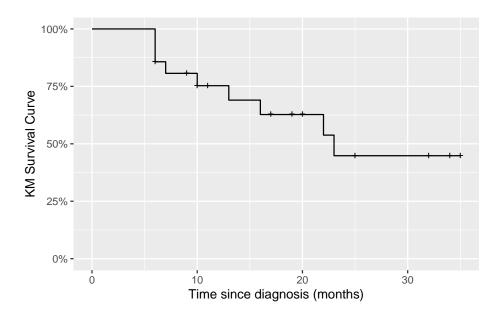

Figure 16: Kaplan-Meier Survival Curve for 6-MP Patients

0.34.2 Kaplan-Meier calculations

Let's compute these estimates and build the chart by hand:

```
library(KMsurv)
library(dplyr)
data(drug6mp)
```

```
drug6mp.v2 =
  drug6mp |>
  as_tibble() |>
  mutate(
   remstat = remstat |>
      case_match(
        1 ~ "partial",
        2 ~ "complete"
      ),
    # renaming to "outcome" while relabeling is just a style choice:
    outcome = relapse |>
      case_match(
       0 ~ "censored",
       1 ~ "relapsed"
  )
km.6mp =
  drug6mp.v2 |>
  summarize(
    .by = t2,
    Relapses = sum(outcome == "relapsed"),
    Censored = sum(outcome == "censored")) |>
  # here we add a start time row, so the graph starts at time 0:
  bind_rows(
    tibble(
      t2 = 0,
     Relapses = 0,
      Censored = 0)
  ) |>
  # sort in time order:
  arrange(t2) |>
```

```
mutate(
    Exiting = Relapses + Censored,
    `Study Size` = sum(Exiting),
    Exited = cumsum(Exiting) |> dplyr::lag(default = 0),
    `At Risk` = `Study Size` - Exited,
    Hazard = Relapses / `At Risk`,
    `KM Factor` = 1 - Hazard,
    `Cumulative Hazard` = cumsum(`Hazard`),
    `KM Survival Curve` = cumprod(`KM Factor`)
)

library(pander)
pander(km.6mp)
```

35	0	1	1	21	20	1	0	1	0.7521	0.4482

0.34.2.1 Summary

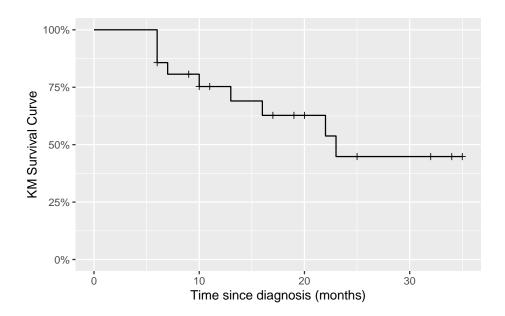

For the 6-MP patients at time 6 months, there are 21 patients at risk. At t=6 there are 3 relapses and 1 censored observations.

The Kaplan-Meier factor is (21-3)/21 = 0.857. The number at risk for the next time (t=7) is 21-3-1=17.

At time 7 months, there are 17 patients at risk. At t=7 there is 1 relapse and 0 censored observations. The Kaplan-Meier factor is (17-1)/17 = 0.941. The Kaplan Meier estimate is $0.857 \times 0.941 = 0.807$. The number at risk for the next time (t=9) is 17-1=16.

Now, let's graph this estimated survival curve using ggplot():

```
library(ggplot2)
conflicts_prefer(dplyr::filter)
km.6mp |>
    ggplot(aes(x = t2, y = `KM Survival Curve`)) +
    geom_step() +
    geom_point(data = km.6mp |> filter(Censored > 0), shape = 3) +
    expand_limits(y = c(0,1), x = 0) +
    xlab('Time since diagnosis (months)') +
    ylab("KM Survival Curve") +
    scale_y_continuous(labels = scales::percent)
```

0.35 Using the survival package in R

We don't have to do these calculations by hand every time; the survival package and several others have functions available to automate many of these tasks (full list: https://cran.r-project.org/web/views/Survival.html).

0.35.1 The Surv function

To use the survival package, the first step is telling R how to combine the exit time and exit reason (censoring versus event) columns. The Surv() function accomplishes this task.

0.35.1.1 Example: Surv() with drug6mp data

```
library(survival)
  drug6mp.v3 =
2
     drug6mp.v2 |>
3
     mutate(
4
       surv2 = Surv(
5
         time = t2,
         event = (outcome == "relapsed")))
  print(drug6mp.v3)
# A tibble: 21 x 7
    pair remstat
                             t2 relapse outcome
                       t1
                                                    surv2
   <int> <chr>
                    <int> <int>
                                   <int> <chr>
                                                   <Surv>
 1
        1 partial
                        1
                             10
                                       1 relapsed
                                                       10
 2
        2 complete
                       22
                              7
                                                       7
                                       1 relapsed
 3
                                                      32+
        3 complete
                        3
                             32
                                       0 censored
        4 complete
 4
                       12
                             23
                                       1 relapsed
                                                      23
 5
        5 complete
                        8
                             22
                                       1 relapsed
                                                      22
 6
        6 partial
                       17
                              6
                                       1 relapsed
                                                       6
 7
        7 complete
                        2
                                       1 relapsed
                             16
                                                      16
 8
        8 complete
                       11
                             34
                                       0 censored
                                                      34+
 9
        9 complete
                       8
                                       0 censored
                                                      32+
                             32
10
      10 complete
                       12
                             25
                                       0 censored
                                                      25+
```

The output of Surv() is a vector of objects with class Surv. When we print this vector:

i 11 more rows

• observations where the event was observed are printed as the event time (for example, surv2 = 10 on line 1)

observations where the event was right-censored are printed as the censoring time with a plus sign (+; for example, surv2 = 32+ on line 3).

0.35.2 The survfit function

Once we have constructed our Surv variable, we can calculate the Kaplan-Meier estimate of the survival curve using the survfit() function.

Note

[1,] 21

The documentation for ?survfit isn't too helpful; the survfit.formula documentation is better.

0.35.2.1 Example: survfit() with drug6mp data

Here we use survfit() to create a survfit object, which contains the Kaplan-Meier estimate:

```
drug6mp.km_model = survfit(
  formula = surv2 ~ 1,
  data = drug6mp.v3)
```

print(drug6mp.km_model)

9

print.survfit() just gives some summary statistics:

23

```
Call: survfit(formula = surv2 ~ 1, data = drug6mp.v3)
    n events median 0.95LCL 0.95UCL
```

16

NA

summary.survfit() shows us the underlying Kaplan-Meier table:

```
summary(drug6mp.km_model)
```

Call: survfit(formula = surv2 ~ 1, data = drug6mp.v3)

time	n.risk	${\tt n.event}$	survival	std.err	lower	95% CI	upper	95% CI
6	21	3	0.857	0.0764		0.720		1.000
7	17	1	0.807	0.0869		0.653		0.996
10	15	1	0.753	0.0963		0.586		0.968
13	12	1	0.690	0.1068		0.510		0.935
16	11	1	0.627	0.1141		0.439		0.896
22	7	1	0.538	0.1282		0.337		0.858
23	6	1	0.448	0.1346		0.249		0.807

summary.survfit() shows us the underlying Kaplan-Meier table:

```
summary(drug6mp.km_model)
```

```
Call: survfit(formula = surv2 ~ 1, data = drug6mp.v3)
```

time	n.risk	${\tt n.event}$	survival	std.err	lower	95% CI	upper	95% CI
6	21	3	0.857	0.0764		0.720		1.000
7	17	1	0.807	0.0869		0.653		0.996
10	15	1	0.753	0.0963		0.586		0.968
13	12	1	0.690	0.1068		0.510		0.935
16	11	1	0.627	0.1141		0.439		0.896
22	7	1	0.538	0.1282		0.337		0.858
23	6	1	0.448	0.1346		0.249		0.807

We can specify which time points we want using the times argument:

```
summary(
     drug6mp.km_model,
    times = c(0, drug6mp.v3$t2))
Call: survfit(formula = surv2 ~ 1, data = drug6mp.v3)
 time n.risk n.event survival std.err lower 95% CI upper 95% CI
    0
                    0
                          1.000
                                  0.0000
                                                 1.000
                                                                1.000

```

?summary.survfit

Summary of a Survival Curve

Description:

Returns a list containing the survival curve, confidence limits for the curve, and other information.

Usage:

```
## S3 method for class 'survfit'
summary(object, times, censored=FALSE, scale=1,
    extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

Arguments:

object: the result of a call to the 'survfit' function.

times: vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If 'censored=T', the default 'times' vector contains all the unique times in 'fit', otherwise the default 'times' vector uses only the event (death) times.

censored: logical value: should the censoring times be included in the output? This is ignored if the 'times' argument is present.

scale: numeric value to rescale the survival time, e.g., if the
 input data to 'survfit' were in days, 'scale = 365.25' would
 scale the output to years.

extend: logical value: if TRUE, prints information for all specified 'times', even if there are no subjects left at the end of the specified 'times'. This is only used if the 'times' argument

is present.

 ${\tt rmean: Show \; restricted \; mean: \; see \; 'print.survfit' \; for \; details}$

...: for future methods

0.35.3 Plotting estimated survival functions

We can plot survfit objects with plot(), autoplot(), or ggsurvplot():

```
library(ggfortify)
autoplot(drug6mp.km_model)
```

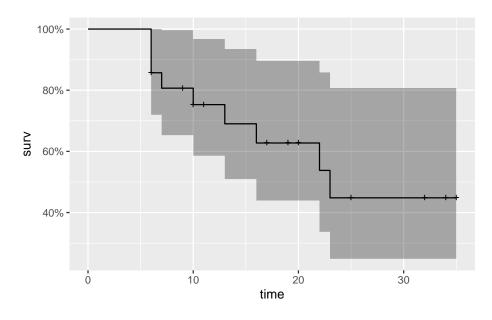

Figure 17: Kaplan-Meier Survival Curve for 6-MP Patients

```
# not shown:
# plot(drug6mp.km_model)

# library(survminer)
# ggsurvplot(drug6mp.km_model)
```

0.35.3.1 quantiles of survival curve

We can extract quantiles with quantile():

```
drug6mp.km_model |>
quantile(p = c(.25, .5)) |>
as_tibble() |>
mutate(p = c(.25, .5)) |>
relocate(p, .before = everything())
```

р	quantile	lower	upper
0.25	13	6	NA
0.50	23	16	NA

0.35.4 Two-sample tests

0.35.4.1 The survdiff function

?survdiff

Test Survival Curve Differences

Description:

Tests if there is a difference between two or more survival curves using the G-rho family of tests, or for a single curve against a known alternative.

Usage:

```
survdiff(formula, data, subset, na.action, rho=0, timefix=TRUE)
```

0.35.4.2 Example: survdiff() with drug6mp data

Now we are going to compare the placebo and 6-MP data. We need to reshape the data to make it usable with the standard survival workflow:

```
library(survival)
drug6mp.v4 =
  drug6mp.v3 |>
  select(pair, remstat, t1, t2, outcome) |>
  # here we are going to change the data from a wide format to long:
  pivot_longer(
    cols = c(t1, t2),
    names_to = "treatment",
    values_to = "exit_time") |>
  mutate(
    treatment = treatment |>
      case_match(
        "t1" ~ "placebo",
        "t2" ~ "6-MP"
      ),
    outcome = if_else(
      treatment == "placebo",
```

```
"relapsed",
   outcome
),
surv = Surv(
   time = exit_time,
   event = (outcome == "relapsed"))
)
```

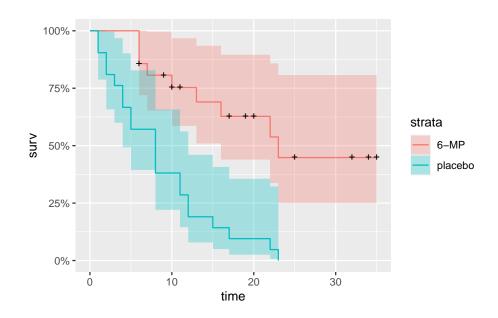

Using this long data format, we can fit a Kaplan-Meier curve for each treatment group simultaneously:

```
drug6mp.km_model2 =
    survfit(
  formula = surv ~ treatment,
  data = drug6mp.v4)
```

We can plot the curves in the same graph:

```
drug6mp.km_model2 |> autoplot()
```

Time to Event Models

We can also perform something like a t-test, where the null hypothesis is that the curves are the same:

```
survdiff(
  formula = surv ~ treatment,
  data = drug6mp.v4)
```

Call:
survdiff(formula = surv ~ treatment, data = drug6mp.v4)

	N	Observed	Expected	$(0-E)^2/E$	$(0-E)^2/V$
treatment=6-MP	21	9	19.3	5.46	16.8
treatment=placebo	21	21	10.7	9.77	16.8

Chisq= 16.8 on 1 degrees of freedom, p= 4e-05

By default, survdiff() ignores any pairing, but we can use strata() to perform something similar to a paired t-test:

```
survdiff(
    formula = surv ~ treatment + strata(pair),
    data = drug6mp.v4)
Call:
survdiff(formula = surv ~ treatment + strata(pair), data = drug6mp.v4)
                   N Observed Expected (O-E)^2/E (O-E)^2/V
treatment=6-MP
                  21
                            9
                                  16.5
                                            3.41
                                                       10.7
                                  13.5
                                            4.17
treatment=placebo 21
                           21
                                                       10.7
Chisq= 10.7 on 1 degrees of freedom, p= 0.001
```

Interestingly, accounting for pairing reduces the significant of the difference.

0.36 Example: Bone Marrow Transplant Data

(Copelan et al., 1991)

- * Treatment
 - allogeneic (from a donor) bone marrow transplant therapy
- * Inclusion criteria
 - acute myeloid leukemia (AML)
 - acute lymphoblastic leukemia (ALL).

- * Possible intermediate events
 - graft vs. host disease (GVHD): an immunological rejection response to the transplant
 - platelet recovery: a return of platelet count to normal levels.

One or the other, both in either order, or neither may occur.

End point events

- relapse of the disease
- death

Any or all of these events may be censored.

0.36.1 KMsurv::bmt data in R

```
library(printr) # inserts help-file output into markdown output
library(KMsurv)
?bmt
```

data from Section 1.3

Description:

The 'bmt' data frame has 137 rows and 22 columns.

Format:

This data frame contains the following columns:

group Disease Group 1-ALL, 2-AML Low Risk, 3-AML High Risk

- t1 Time To Death Or On Study Time
- t2 Disease Free Survival Time (Time To Relapse, Death Or End Of Study)
- d1 Death Indicator 1-Dead 0-Alive
- d2 Relapse Indicator 1-Relapsed, 0-Disease Free
- d3 Disease Free Survival Indicator 1-Dead Or Relapsed, 0-Alive Disease Free)
- ta Time To Acute Graft-Versus-Host Disease
- da Acute GVHD Indicator 1-Developed Acute GVHD 0-Never Developed Acute GVHD)
- tc Time To Chronic Graft-Versus-Host Disease
- dc Chronic GVHD Indicator 1-Developed Chronic GVHD 0-Never Developed Chronic GVHD
- tp Time To Chronic Graft-Versus-Host Disease
- z1 Patient Age In Years
- z2 Donor Age In Years
- z3 Patient Sex: 1-Male, 0-Female

- z4 Donor Sex: 1-Male, 0-Female
- z5 Patient CMV Status: 1-CMV Positive, 0-CMV Negative
- z6 Donor CMV Status: 1-CMV Positive, 0-CMV Negative
- z7 Waiting Time to Transplant In Days
- z8 FAB: 1-FAB Grade 4 Or 5 and AML, 0-Otherwise
- z9 Hospital: 1-The Ohio State University, 2-Alferd , 3-St. Vincent, 4-Hahnemann
- z10 MTX Used as a Graft-Versus-Host- Prophylactic: 1-Yes 0-No

Klein and Moeschberger (1997) _Survival Analysis Techniques for Censored and truncated data_, Springer.

Examples:

data(bmt)

0.36.2 Analysis plan

- We concentrate for now on disease-free survival (t2 and d3) for the three risk groups, ALL, AML Low Risk, and AML High Risk.
- We will construct the Kaplan-Meier survival curves, compare them, and test for differences.
- We will construct the cumulative hazard curves and compare them.
- We will estimate the hazard functions, interpret, and compare them.

0.36.3 Survival Function Estimate and Variance

$$\hat{S}(t) = \prod_{t_i < t} \left[1 - \frac{d_i}{Y_i} \right]$$

where Y_i is the group at risk at time t_i .

The estimated variance of $\hat{S}(t)$ is (Greenwood's formula)

$$\hat{\text{Var}}\left(\hat{S}(t)\right) = \hat{S}(t)^2 \sum_{t_i < t} \frac{d_i}{Y_i(Y_i - d_i)}$$

which we can use for confidence intervals for a survival function or a difference of survival functions.

Kaplan-Meier survival curves

```
library(KMsurv)
library(survival)
data(bmt)

bmt =
   bmt |>
   as_tibble() |>
   mutate(
   group =
      group |>
      factor(
      labels = c("ALL","Low Risk AML","High Risk AML")),
   surv = Surv(t2,d3))

km_model1 = survfit(
   formula = surv ~ group,
   data = bmt)
```

```
library(ggfortify)
autoplot(
   km_model1,
   conf.int = TRUE,
   ylab = "Pr(disease-free survival)",
   xlab = "Time since transplant (days)") +
   theme_bw() +
   theme(legend.position="bottom")
```

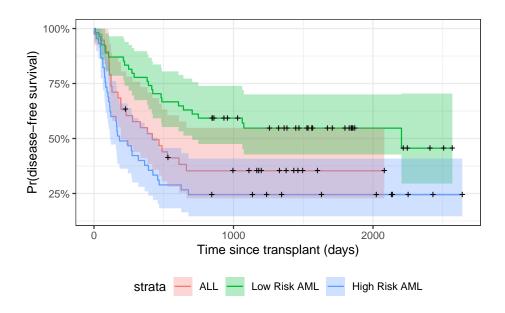

Figure 18: Disease-Free Survival by Disease Group

0.36.3.1 Understanding Greenwood's formula (optional)

To see where Greenwood's formula comes from, let $x_i = Y_i - d_i$. We approximate the solution treating each time as independent, with Y_i fixed

and ignore randomness in times of failure and we treat x_i as independent binomials $Bin(Y_i, p_i)$. Letting S(t) be the "true" survival function

$$\begin{split} \hat{S}(t) &= \prod_{t_i < t} x_i / Y_i \\ S(t) &= \prod_{t_i < t} p_i \\ \\ \frac{\hat{S}(t)}{S(t)} &= \prod_{t_i < t} \frac{x_i}{p_i Y_i} = \prod_{t_i < t} \frac{\hat{p}_i}{p_i} \end{split}$$

$$\begin{split} \frac{\overleftarrow{S}(t)}{S(t)} &= \prod_{t_i < t} \frac{\iota}{p_i Y_i} = \prod_{t_i < t} \frac{\iota}{p_i} \\ &= \prod_{t_i < t} \left(1 + \frac{\widehat{p}_i - p_i}{p_i} \right) \\ &\approx 1 + \sum_{t_i < t} \frac{\widehat{p}_i - p_i}{p_i} \end{split}$$

$$\begin{split} \operatorname{Var}\left(\frac{\hat{S}(t)}{S(t)}\right) &\approx \operatorname{Var}\left(1 + \sum_{t_i < t} \frac{\hat{p}_i - p_i}{p_i}\right) \\ &= \sum_{t_i < t} \frac{1}{p_i^2} \frac{p_i (1 - p_i)}{Y_i} \\ &= \sum_{t_i < t} \frac{(1 - p_i)}{p_i Y_i} \approx \sum_{t_i < t} \frac{(1 - x_i / Y_i)}{x_i} \\ &= \sum_{t_i < t} \frac{Y_i - x_i}{x_i Y_i} = \sum_{t_i < t} \frac{d_i}{Y_i (Y_i - d_i)} \end{split}$$

$$\operatorname{Var}\left(\hat{S}(t)\right) \approx \hat{S}(t)^2 \sum_{t_i < t} \frac{d_i}{Y_i (Y_i - d_i)} \end{split}$$

0.36.4 Test for differences among the disease groups

Here we compute a chi-square test for assocation between disease group (group) and disease-free survival:

Call:

survdiff(formula = surv ~ group, data = bmt)

	N	Observed	Expected	$(0-E)^2/E$	$(0-E)^2/V$
group=ALL	38	24	21.9	0.211	0.289
group=Low Risk AML	54	25	40.0	5.604	11.012
group=High Risk AML	45	34	21.2	7.756	10.529

Chisq= 13.8 on 2 degrees of freedom, p= 0.001

0.36.5 Cumulative Hazard

$$\begin{split} h(t) &\stackrel{\text{def}}{=} P(T=t|T\geq t) \\ &= \frac{p(T=t)}{P(T\geq t)} \\ &= -\frac{d}{dt} \text{log}\left\{S(t)\right\} \end{split}$$

The cumulative hazard (or integrated hazard) function is

$$H(t) \stackrel{\text{def}}{=} \int_0^t h(t)dt$$

Since $h(t) = -\frac{d}{dt} \mathrm{log} \left\{ S(t) \right\}$ as shown above, we have:

$$H(t) = -\log\{S\}(t)$$

So we can estimate H(t) as:

$$\begin{split} \hat{H}(t) &= -\mathrm{log}\left\{\hat{S}(t)\right\} \\ &= -\mathrm{log}\left\{\prod_{t_i < t} \left[1 - \frac{d_i}{Y_i}\right]\right\} \\ &= -\sum_{t_i < t} \mathrm{log}\left\{1 - \frac{d_i}{Y_i}\right\} \end{split}$$

This is the Kaplan-Meier (product-limit) estimate of cumulative hazard.

0.36.5.1 Example: Cumulative Hazard Curves for Bone-Marrow Transplant (bmt) data

```
autoplot(
  fun = "cumhaz",
  km_model1,
  conf.int = FALSE,
  ylab = "Cumulative hazard (disease-free survival)",
  xlab = "Time since transplant (days)") +
  theme_bw() +
  theme(legend.position="bottom")
```

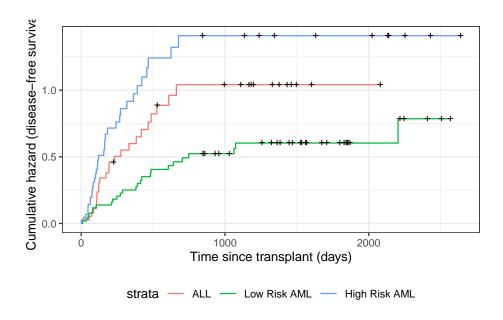

Figure 19: Disease-Free Cumulative Hazard by Disease Group

0.37 Nelson-Aalen Estimates of Cumulative Hazard and Survival

The point hazard at time t_i can be estimated by d_i/Y_i , which leads to the Nelson-Aalen estimator of the cumulative hazard:

$$\hat{H}_{NA}(t) \stackrel{\mathrm{def}}{=} \sum_{t_i < t} \frac{d_i}{Y_i}$$

The variance of this estimator is approximately:

$$\begin{split} \hat{\text{Var}}\left(\hat{H}_{NA}(t)\right) &= \sum_{t_i < t} \frac{(d_i/Y_i)(1 - d_i/Y_i)}{Y_i} \\ &\approx \sum_{t_i < t} \frac{d_i}{Y_i^2} \end{split}$$

Since $S(t) = \exp\{-H(t)\}$, the Nelson-Aalen cumulative hazard estimate can be converted into an alternate estimate of the survival function:

$$\begin{split} \hat{S}_{NA}(t) &= \exp\left\{-\hat{H}_{NA}(t)\right\} \\ &= \exp\left\{-\sum_{t_i < t} \frac{d_i}{Y_i}\right\} \\ &= \prod_{t_i < t} \exp\left\{-\frac{d_i}{Y_i}\right\} \end{split}$$

Compare these with the corresponding Kaplan-Meier estimates:

$$\begin{split} \hat{H}_{KM}(t) &= -\sum_{t_i < t} \log \left\{ 1 - \frac{d_i}{Y_i} \right\} \\ \hat{S}_{KM}(t) &= \prod_{t_i < t} \left[1 - \frac{d_i}{Y_i} \right] \end{split}$$

The product limit estimate and the Nelson-Aalen estimate often do not differ by much. The latter is considered more accurate in small samples and also directly estimates the cumulative hazard. The "fleming-harrington" method for survfit() reduces to Nelson-Aalen when the data are unweighted. We can also estimate the cumulative hazard as the negative log of the KM survival function estimate.

0.37.1 Application to bmt dataset

```
na_fit = survfit(
 formula = surv ~ group,
  type = "fleming-harrington",
  data = bmt)
km_fit = survfit(
  formula = surv ~ group,
  type = "kaplan-meier",
  data = bmt)
km_and_na =
 bind_rows(
    .id = "model",
    "Kaplan-Meier" = km_fit |> fortify(surv.connect = TRUE),
    "Nelson-Aalen" = na_fit |> fortify(surv.connect = TRUE)
  ) |>
  as_tibble()
km_and_na |>
  ggplot(aes(x = time, y = surv, col = model)) +
  geom_step() +
 facet_grid(. ~ strata) +
  theme_bw() +
  ylab("S(t) = P(T>=t)") +
  xlab("Survival time (t, days)") +
  theme(legend.position = "bottom")
```

Figure 20: Kaplan-Meier and Nelson-Aalen Survival Function Estimates, stratified by disease group

The Kaplan-Meier and Nelson-Aalen survival estimates are very similar for this dataset.

0.38 Proportional Hazards Models

Configuring R

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
```

```
library(ggeasy) # help with graphics
library(dplyr) # manipulate data
library(haven) # import Stata files
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
conflicts_prefer(dplyr::filter)
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
options('digits' = 4)
```

0.39 The proportional hazards model

0.39.1 Background on the Proportional Hazards Model

The exponential distribution has constant hazard:

$$f(t) = \lambda e^{-\lambda t}$$

$$S(t) = e^{-\lambda t}$$

$$h(t) = \lambda$$

Let's make two generalizations. First, we let the hazard depend on some covariates x_1, x_2, \ldots, x_p ; we will indicate this dependence by extending our notation for hazard:

$$h(t|x) \stackrel{\mathrm{def}}{=} p(T = t|T \ge t, X = x)$$

Second, we let the base hazard depend on t, but not on the covariates (for now). We can do this using either parametric or semi-parametric approaches.

0.39.2 Cox's Proportional Hazards Model

The generalization is that the hazard function is

$$\begin{split} h(t|x) &= h_0(t)\theta(x) \\ \theta(x) &= \exp\left\{\eta(x)\right\} \\ \eta(x) &= x'\beta \\ &\stackrel{\text{def}}{=} \beta_1 x_1 + \dots + \beta_p x_p \end{split}$$

The relationship between h(t|x) and $\eta(x)$ has a log link (that is, $\log\{h(t|x)\} = \log\{h_0(t)\} + \eta(x)$), as in a generalized linear model.

This model is **semi-parametric**, because the linear predictor depends on estimated parameters but the base hazard function is unspecified. There is no constant term in $\eta(x)$, because it is absorbed in the base hazard.

Alternatively, we could define
$$\beta_0(t) = \log\{h_0(t)\}$$
, and then $\eta(x,t) = \beta_0(t) + \beta_1 x_1 + \dots + \beta_p x_p$.

For two different individuals with covariate patterns x_1 and x_2 , the ratio of the hazard functions (a.k.a. **hazard ratio**, a.k.a. **relative hazard**) is:

$$\begin{split} \frac{h(t|x_1)}{h(t|x_2)} &= \frac{h_0(t)\theta(x_1)}{h_0(t)\theta(x_2)} \\ &= \frac{\theta(x_1)}{\theta(x_2)} \end{split}$$

Under the proportional hazards model, this ratio (a.k.a. proportion) does not depend on t. This property is a structural limitation of the model; it is called the **proportional hazards assumption**.

Definition 0.12 (proportional hazards). A conditional probability distribution p(T|X) has **proportional hazards** if the hazard ratio $h(t|x_1)/h(t|x_2)$ does not depend on t. Mathematically, it can be written as:

$$\frac{h(t|x_1)}{h(t|x_2)} = \theta(x_1, x_2)$$

As we saw above, Cox's proportional hazards model has this property, with $\theta(x_1,x_2)=rac{\theta(x_1)}{\theta(x_2)}.$

Note

We are using two similar notations, $\theta(x_1, x_2)$ and $\theta(x)$. We can link these notations if we define $\theta(x) \stackrel{\text{def}}{=} \theta(x, 0)$ and $\theta(0) = 1$.

It also has additional notable properties:

$$\begin{split} \frac{h(t|x_1)}{h(t|x_2)} &= \frac{\theta(x_1)}{\theta(x_2)} \\ &= \frac{\exp{\{\eta(x_1)\}}}{\exp{\{\eta(x_2)\}}} \\ &= \exp{\{\eta(x_1) - \eta(x_2)\}} \\ &= \exp{\{x_1'\beta - x_2'\beta\}} \\ &= \exp{\{(x_1 - x_2)'\beta\}} \end{split}$$

Hence on the log scale, we have:

$$\begin{split} \log\left\{\frac{h(t|x_1)}{h(t|x_2)}\right\} &= \eta(x_1) - \eta(x_2) \\ &= x_1'\beta - x_2'\beta \\ &= (x_1 - x_2)'\beta \end{split}$$

If only one covariate x_i is changing, then:

$$\begin{split} \log \left\{ \frac{h(t|x_1)}{h(t|x_2)} \right\} &= (x_{1j} - x_{2j}) \cdot \beta_j \\ &\propto (x_{1j} - x_{2j}) \end{split}$$

That is, under Cox's model $h(t|x) = h_0(t) \exp\{x'\beta\}$, the log of the hazard ratio is proportional to the difference in x_j , with the proportionality coefficient equal to β_j .

Further,

$$\log\left\{h(t|x)\right\} = \log\left\{h_0(t)\right\} + x'\beta$$

That is, the covariate effects are additive on the log-hazard scale.

See also:

 $https://en.wikipedia.org/wiki/Proportional_hazards_model\#Why_it_is~called~\%22 proportional\%22$

0.39.3 Additional properties of the proportional hazards model

If $h(t|x) = h_0(t)\theta(x)$, then:

0.39.3.1 Cumulative hazards are also proportional to $H_0(t)$

$$\begin{split} H(t|x) &\stackrel{\text{def}}{=} \int_{u=0}^t h(u) du \\ &= \int_{u=0}^t h_0(u) \theta(x) du \\ &= \theta(x) \int_{u=0}^t h_0(u) du \\ &= \theta(x) H_0(t) \end{split}$$

where $H_0(t) \stackrel{\text{def}}{=} H(t|0) = \int_{u=0}^{t} h_0(u) du$.

0.39.3.2 Survival functions are exponential multiples of $S_0(t)$

$$\begin{split} S(t|x) &= \exp\left\{-H(t|x)\right\} \\ &= \exp\left\{-\theta(x) \cdot H_0(t)\right\} \\ &= \left(\exp\left\{-H_0(t)\right\}\right)^{\theta(x)} \\ &= \left(S_0(t)\right)^{\theta(x)} \end{split}$$

where $S_0(t) \stackrel{\text{def}}{=} P(T \ge t | X = 0)$ is the survival function for an individual whose covariates are all equal to their default values.

0.39.4 Testing the proportional hazards assumption

The Nelson-Aalen estimate of the cumulative hazard is usually used for estimates of the hazard and often the cumulative hazard.

If the hazards of the three groups are proportional, that means that the ratio of the hazards is constant over t. We can test this using the ratios of the estimated cumulative hazards, which also would be proportional, as shown above.

```
library(KMsurv)
library(survival)
data(bmt)
bmt =
  bmt |>
  as_tibble() |>
  mutate(
    group =
      group |>
      factor(
        labels = c("ALL","Low Risk AML","High Risk AML")))
nafit = survfit(
  formula = Surv(t2,d3) ~ group,
  type = "fleming-harrington",
  data = bmt)
bmt_curves = tibble(timevec = 1:1000)
sf1 <- with(nafit[1], stepfun(time,c(1,surv)))</pre>
sf2 <- with(nafit[2], stepfun(time,c(1,surv)))</pre>
sf3 <- with(nafit[3], stepfun(time,c(1,surv)))
```

```
bmt_curves =
  bmt_curves |>
  mutate(
    cumhaz1 = -log(sf1(timevec)),
    cumhaz2 = -log(sf2(timevec)),
    cumhaz3 = -log(sf3(timevec)))
library(ggplot2)
bmt_rel_hazard_plot =
  bmt_curves |>
  ggplot(
   aes(
     x = timevec,
      y = cumhaz1/cumhaz2)
  ) +
  geom_line(aes(col = "ALL/Low Risk AML")) +
  ylab("Hazard Ratio") +
  xlab("Time") +
  ylim(0,6) +
  geom_line(aes(y = cumhaz3/cumhaz1, col = "High Risk AML/ALL")) +
  geom_line(aes(y = cumhaz3/cumhaz2, col = "High Risk AML/Low Risk AML")) +
  theme_bw() +
  labs(colour = "Comparison") +
  theme(legend.position="bottom")
print(bmt_rel_hazard_plot)
```

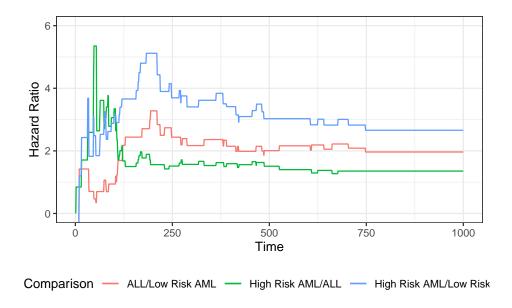

Figure 21: Hazard Ratios by Disease Group

We can zoom in on 30-300 days to take a closer look:

```
bmt_rel_hazard_plot + xlim(c(30,300))
```

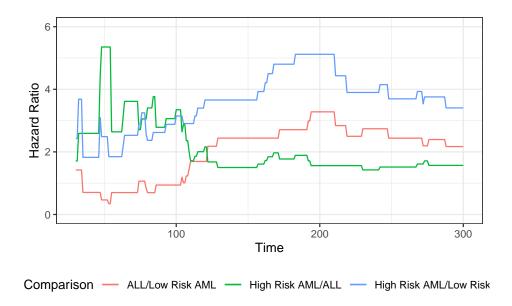

Figure 22: Hazard Ratios by Disease Group (30-300 Days)

0.39.5 Smoothed hazard functions

The Nelson-Aalen estimate of the cumulative hazard is usually used for estimates of the hazard. Since the hazard is the derivative of the cumulative hazard, we need a smooth estimate of the cumulative hazard, which is provided by smoothing the step-function cumulative hazard.

The R package muhaz handles this for us. What we are looking for is whether the hazard function is more or less the same shape, increasing, decreasing, constant, etc. Are the hazards "proportional"?

```
plot(
    survfit(Surv(t2,d3)~group,data=bmt),
```

```
col=1:3,
lwd=2,
fun="cumhaz",
mark.time = TRUE)
legend("bottomright",c("ALL","Low Risk AML","High Risk AML"),col=1:3,lwd=2)
```

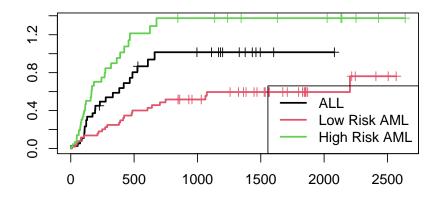

Figure 23: Disease-Free Cumulative Hazard by Disease Group

```
library(muhaz)
muhaz(bmt$t2,bmt$d3,bmt$group=="High Risk AML") |> plot(lwd=2,col=3)
muhaz(bmt$t2,bmt$d3,bmt$group=="ALL") |> lines(lwd=2,col=1)
muhaz(bmt$t2,bmt$d3,bmt$group=="Low Risk AML") |> lines(lwd=2,col=2)
legend("topright",c("ALL","Low Risk AML","High Risk AML"),col=1:3,lwd=2)
```

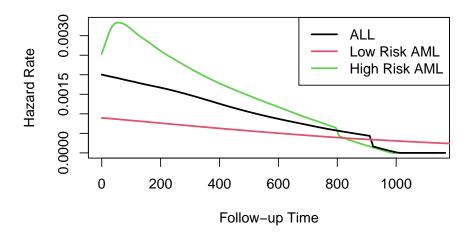

Figure 24: Smoothed Hazard Rate Estimates by Disease Group

Group 3 was plotted first because it has the highest hazard.

We will see that except for an initial blip in the high risk AML group, the hazards look roughly proportional. They are all strongly decreasing.

0.39.6 Fitting the Proportional Hazards Model

How do we fit a proportional hazards regression model? We need to estimate the coefficients of the covariates, and we need to estimate the base hazard $h_0(t)$. For the covariates, supposing for simplicity that there are no tied event times, let the event times for the whole data set be t_1, t_2, \ldots, t_D . Let the risk set at time t_i be $R(t_i)$ and

$$\begin{split} \eta(x) &= \beta_1 x_1 + \dots + \beta_p x_p \\ \theta(x) &= e^{\eta(x)} \\ h(t|X=x) &= h_0(t) e^{\eta(x)} = \theta(x) h_0(t) \end{split}$$

Conditional on a single failure at time t, the probability that the event is due to subject $f \in R(t)$ is approximately

$$\begin{split} \Pr(f \text{ fails}|1 \text{ failure at } t) &= \frac{h_0(t)e^{\eta(x_f)}}{\sum_{k \in R(t)} h_0(t)e^{\eta(x_f)}} \\ &= \frac{\theta(x_f)}{\sum_{k \in R(t)} \theta(x_k)} \end{split}$$

The logic behind this has several steps. We first fix (ex post) the failure times and note that in this discrete context, the probability p_j that a subject j in the risk set fails at time t is just the hazard of that subject at that time.

If all of the p_i are small, the chance that exactly one subject fails is

$$\sum_{k \in R(t)} p_k \left[\prod_{m \in R(t), m \neq k} (1 - p_m) \right] \approx \sum_{k \in R(t)} p_k$$

If subject i is the one who experiences the event of interest at time t_i , then the **partial likelihood** is

$$\mathcal{L}^*(\boldsymbol{\beta}|T) = \prod_i \frac{\theta(\boldsymbol{x}_i)}{\sum_{k \in R(t_i)} \theta(\boldsymbol{x}_k)}$$

and we can numerically maximize this with respect to the coefficients β that specify $\eta(x) = x'\beta$. When there are tied event times adjustments

need to be made, but the likelihood is still similar. Note that we don't need to know the base hazard to solve for the coefficients.

Once we have coefficient estimates $\hat{\beta} = (\hat{\beta}_1, \dots, \hat{\beta}_p)$, this also defines $\hat{\eta}(x)$ and $\hat{\theta}(x)$ and then the estimated base cumulative hazard function is

$$\hat{H}(t) = \sum_{t_i < t} \frac{d_i}{\sum_{k \in R(t_i)} \theta(x_k)}$$

which reduces to the Nelson-Aalen estimate when there are no covariates. There are numerous other estimates that have been proposed as well.

0.40 Cox Model for the bmt data

0.40.1 Fit the model

```
bmt.cox <- coxph(Surv(t2, d3) ~ group, data = bmt)</pre>
  summary(bmt.cox)
Call:
coxph(formula = Surv(t2, d3) ~ group, data = bmt)
 n= 137, number of events= 83
                     coef exp(coef) se(coef)
                                                  z Pr(>|z|)
                              0.563
                                        0.287 -2.00
groupLow Risk AML
                   -0.574
                                                        0.046 *
                                        0.267 1.43
groupHigh Risk AML 0.383
                              1.467
                                                       0.152
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
                   exp(coef) exp(-coef) lower .95 upper .95
groupLow Risk AML
                       0.563
                                   1.776
                                             0.321
```

groupHigh Risk AML 1.467 0.682 0.869 2.478

```
Concordance= 0.625 (se = 0.03)

Likelihood ratio test= 13.4 on 2 df, p=0.001

Wald test = 13 on 2 df, p=0.001

Score (logrank) test = 13.8 on 2 df, p=0.001
```

The table provides hypothesis tests comparing groups 2 and 3 to group 1. Group 3 has the highest hazard, so the most significant comparison is not directly shown.

The coefficient 0.3834 is on the log-hazard-ratio scale, as in log-risk-ratio. The next column gives the hazard ratio 1.4673, and a hypothesis (Wald) test.

The (not shown) group 3 vs. group 2 log hazard ratio is 0.3834 + 0.5742 = 0.9576. The hazard ratio is then $\exp(0.9576)$ or 2.605.

Inference on all coefficients and combinations can be constructed using coef(bmt.cox) and vcov(bmt.cox) as with logistic and poisson regression.

Concordance is agreement of first failure between pairs of subjects and higher predicted risk between those subjects, omitting non-informative pairs.

The Rsquare value is Cox and Snell's pseudo R-squared and is not very useful.

summary() prints three tests for whether the model with the group covariate is better than the one without

- Likelihood ratio test (chi-squared)
- Wald test (also chi-squared), obtained by adding the squares of the z-scores
- Score = log-rank test, as with comparison of survival functions.

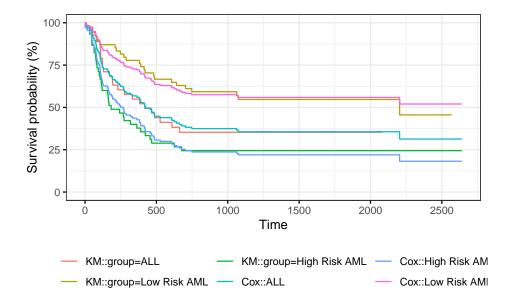

The likelihood ratio test is probably best in smaller samples, followed by the Wald test.

0.40.2 Survival Curves from the Cox Model

We can take a look at the resulting group-specific curves:

```
#| fig-cap: "Survival Functions for Three Groups by KM and Cox Model"
km_fit = survfit(Surv(t2, d3) ~ group, data = as.data.frame(bmt))
cox_fit = survfit(
  bmt.cox,
  newdata =
    data.frame(
      group = unique(bmt$group),
      row.names = unique(bmt$group)))
library(survminer)
list(KM = km_fit, Cox = cox_fit) |>
  survminer::ggsurvplot(
    # facet.by = "group",
    legend = "bottom",
    legend.title = "",
    combine = TRUE,
    fun = 'pct',
    size = .5,
    ggtheme = theme_bw(),
    conf.int = FALSE,
    censor = FALSE) |>
  suppressWarnings() # ggsurvplot() throws some warnings that aren't too worrying
```

Time to Event Models

When we use survfit() with a Cox model, we have to specify the covariate levels we are interested in; the argument newdata should include a data.frame with the same named columns as the predictors in the Cox model and one or more levels of each.

Otherwise (that is, if the newdata argument is missing), a curve is produced for a single "pseudo" subject with covariate values equal to the means component of the fit.

The resulting curve(s) almost never make sense, but the default remains due to an unwarranted attachment to the option shown by some users and by other packages.

Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about

equal numbers of observations for each. The "mean" covariate level will be 0.5 – is this a flying pig?

0.40.3 Examining survfit

```
survfit(Surv(t2, d3)~group,data=bmt)
Call: survfit(formula = Surv(t2, d3) ~ group, data = bmt)
                     n events median 0.95LCL 0.95UCL
group=ALL
                    38
                           24
                                 418
                                          194
                                                   NA
group=Low Risk AML
                    54
                           25
                                2204
                                         704
                                                   NA
group=High Risk AML 45

0.41 Adjustment for Ties (optional)

0.41.1

At each time t_i at which more than one of the subjects has an event, let d_i be the number of events at that time, D_i the set of subjects with events at that time, and let s_i be a covariate vector for an artificial subject obtained by adding up the covariate values for the subjects with an event at time t_i . Let

$$\bar{\eta}_i = \beta_1 s_{i1} + \dots + \beta_p s_{ip}$$

and $\bar{\theta}_i = \exp{\{\bar{\eta}_i\}}$.

Let s_i be a covariate vector for an artificial subject obtained by adding up the covariate values for the subjects with an event at time t_i . Note that

$$\begin{split} \bar{\eta}_i &= \sum_{j \in D_i} \beta_1 x_{j1} + \dots + \beta_p x_{jp} \\ &= \beta_1 s_{i1} + \dots + \beta_p s_{ip} \\ \bar{\theta}_i &= \exp\left\{\bar{\eta}_i\right\} \\ &= \prod_{j \in D_i} \theta_i \end{split}$$

0.41.1.1 Breslow's method for ties

Breslow's method estimates the partial likelihood as

$$\begin{split} L(\beta|T) &= \prod_i \frac{\bar{\theta}_i}{[\sum_{k \in R(t_i)} \theta_k]^{d_i}} \\ &= \prod_i \prod_{j \in D_i} \frac{\theta_j}{\sum_{k \in R(t_i)} \theta_k} \end{split}$$

This method is equivalent to treating each event as distinct and using the non-ties formula. It works best when the number of ties is small. It is the default in many statistical packages, including PROC PHREG in SAS.

0.41.1.2 Efron's method for ties

The other common method is Efron's, which is the default in R.

$$L(\beta|T) = \prod_i \frac{\bar{\theta}_i}{\prod_{j=1}^{d_i} [\sum_{k \in R(t_i)} \theta_k - \frac{j-1}{d_i} \sum_{k \in D_i} \theta_k]}$$

This is closer to the exact discrete partial likelihood when there are many ties.

The third option in R (and an option also in SAS as discrete) is the "exact" method, which is the same one used for matched logistic regression.

0.41.1.3 Example: Breslow's method

Suppose as an example we have a time t where there are 20 individuals at risk and three failures. Let the three individuals have risk parameters $\theta_1, \theta_2, \theta_3$ and let the sum of the risk parameters of the remaining 17 individuals be θ_R . Then the factor in the partial likelihood at time t using Breslow's method is

$$\left(\frac{\theta_1}{\theta_R+\theta_1+\theta_2+\theta_3}\right)\left(\frac{\theta_2}{\theta_R+\theta_1+\theta_2+\theta_3}\right)\left(\frac{\theta_3}{\theta_R+\theta_1+\theta_2+\theta_3}\right)$$

If on the other hand, they had died in the order 1,2, 3, then the contribution to the partial likelihood would be:

$$\left(\frac{\theta_1}{\theta_R + \theta_1 + \theta_2 + \theta_3}\right) \left(\frac{\theta_2}{\theta_R + \theta_2 + \theta_3}\right) \left(\frac{\theta_3}{\theta_R + \theta_3}\right)$$

as the risk set got smaller with each failure. The exact method roughly averages the results for the six possible orderings of the failures.

0.41.1.4 Example: Efron's method

But we don't know the order they failed in, so instead of reducing the denominator by one risk coefficient each time, we reduce it by the same fraction. This is Efron's method.

$$\left(\frac{\theta_1}{\theta_R+\theta_1+\theta_2+\theta_3}\right)\left(\frac{\theta_2}{\theta_R+2(\theta_1+\theta_2+\theta_3)/3}\right)\left(\frac{\theta_3}{\theta_R+(\theta_1+\theta_2+\theta_3)/3}\right)$$

0.42 Building Cox Proportional Hazards models

Configuring R

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
library(ggfortify) # help with graphics
library(ggeasy) # help with graphics
library(survival) # survival analysis
library(survminer) # survival analysis graphics
library(dplyr) # manipulate data
library(haven) # import Stata files
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(fs) # filesystem path manipulations
library(KMsurv) # datasets from Klein and Moeschberger
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
conflicts_prefer(dplyr::filter)
conflicts_prefer(ggplot2::autoplot)
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
options('digits' = 4)
legend_text_size = 9
```

0.43 Building Cox Proportional Hazards models

0.43.1 hodg Lymphoma Data Set from KMsurv

0.43.1.1 Participants

43 bone marrow transplant patients at Ohio State University (Avalos 1993)

0.43.1.2 Variables

- dtype: Disease type (Hodgkin's or non-Hodgkins lymphoma)
- gtype: Bone marrow graft type:
- allogeneic: from HLA-matched sibling
- autologous: from self (prior to chemo)
- time: time to study exit
- delta: study exit reason (death/relapse vs censored)
- wtime: waiting time to transplant (in months)
- score: Karnofsky score:
- 80–100: Able to carry on normal activity and to work; no special care needed.
- 50–70: Unable to work; able to live at home and care for most personal needs; varying amount of assistance needed.
- 10–60: Unable to care for self; requires equivalent of institutional or hospital care; disease may be progressing rapidly.

0.43.1.3 Data

```
data(hodg, package = "KMsurv")
  hodg2 = hodg >
    as_tibble() |>
    mutate(

0.44 Diagnostic graphs for proportional hazards assumption

0.44.1 Analysis plan

- survival function for the four combinations of disease type and graft type.
- observed (nonparametric) vs. expected (semiparametric) survival functions.
- complementary log-log survival for the four groups.

0.44.2 Kaplan-Meier survival functions

```
km_model = survfit(
  formula = surv ~ dtype + gtype,
  data = hodg2)

km_model |>
  autoplot(conf.int = FALSE) +
```

```
theme_bw() +
theme(
  legend.position="bottom",
  legend.title = element_blank(),
  legend.text = element_text(size = legend_text_size)
) +
guides(col=guide_legend(ncol=2)) +
ylab('Survival probability, S(t)') +
xlab("Time since transplant (days)")
```

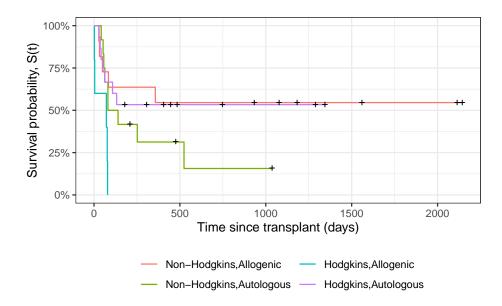

Figure 25: Kaplan-Meier Survival Curves for HOD/NHL and Allo/Auto Grafts

0.44.3 Observed and expected survival curves

```
# we need to create a tibble of covariate patterns;
# we will set score and wtime to mean values for disease and graft types:
means = hodg2 |>
  summarize(
    .by = c(dtype, gtype),
    score = mean(score),
    wtime = mean(wtime)) |>
  arrange(dtype, gtype) |>
  mutate(strata = paste(dtype, gtype, sep = ",")) |>
  as.data.frame()
# survfit.coxph() will use the rownames of its `newdata`
# argument to label its output:
rownames(means) = means$strata
cox_model =
  hodg.cox1 |>
  survfit(
    data = hodg2, # ggsurvplot() will need this
    newdata = means)
# I couldn't find a good function to reformat `cox_model` for ggplot,
# so I made my own:
stack_surv_ph = function(cox_model)
  cox_model$surv |>
    as_tibble() |>
    mutate(time = cox_model$time) |>
    pivot_longer(
      cols = -time,
```

```
names_to = "strata",
     values_to = "surv") |>
   mutate(
      cumhaz = -log(surv),
     model = "Cox PH")
}
km_and_cph =
 km_model |>
 fortify(surv.connect = TRUE) |>
 mutate(
   strata = trimws(strata),
   model = "Kaplan-Meier",
   cumhaz = -log(surv)) |>
 bind_rows(stack_surv_ph(cox_model))
km_and_cph |>
 ggplot(aes(x = time, y = surv, col = model)) +
 geom_step() +
 facet_wrap(~strata) +
 theme_bw() +
 ylab("S(t) = P(T>=t)") +
 xlab("Survival time (t, days)") +
 theme(legend.position = "bottom")
```

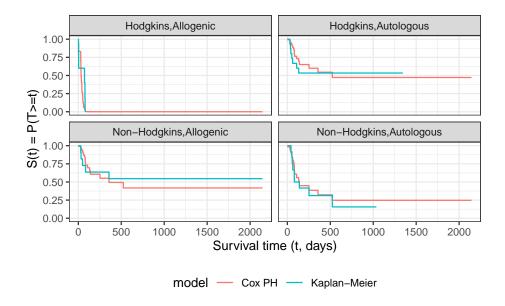

Figure 26: Observed and expected survival curves for bmt data

0.44.4 Cumulative hazard (log-scale) curves

Also known as "complementary log-log (clog-log) survival curves".

```
na_model = survfit(
  formula = surv ~ dtype + gtype,
  data = hodg2,
  type = "fleming")

na_model |> survminer::ggsurvplot(
  legend = "bottom",
  legend.title = "",
  ylab = "log(Cumulative Hazard)",
```

```
xlab = "Time since transplant (days, log-scale)",
fun = 'cloglog',
size = .5,
ggtheme = theme_bw(),
conf.int = FALSE,
censor = TRUE) +
guides(
   col =
       guide_legend(
       ncol = 2,
       label.theme =
       element_text(
       size = legend_text_size)))
```

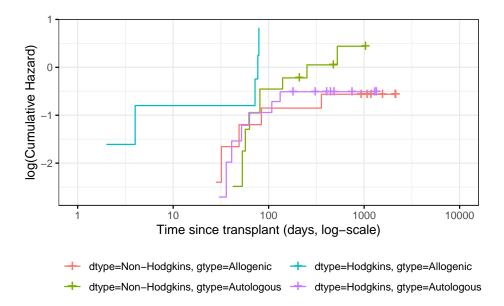

Figure 27: Complementary log-log survival curves - Nelson-Aalen estimates

Let's compare these empirical (i.e., non-parametric) curves with the fitted curves from our coxph() model:

```
cox_model |>
  survminer::ggsurvplot(
    facet_by = "",
    legend = "bottom",
    legend.title = "",
    ylab = "log(Cumulative Hazard)",
    xlab = "Time since transplant (days, log-scale)",
    fun = 'cloglog',
    size = .5,
```

```
ggtheme = theme_bw(),
  censor = FALSE, # doesn't make sense for cox model
  conf.int = FALSE) +
guides(
  col =
    guide_legend(
    ncol = 2,
    label.theme =
    element_text(
       size = legend_text_size)))
```

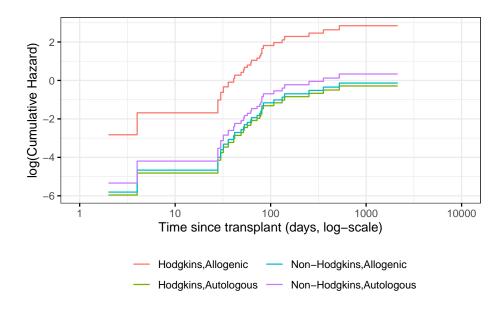

Figure 28: Complementary log-log survival curves - PH estimates

Now let's overlay these cumulative hazard curves:

```
na_and_cph =
 na_model |>
 fortify(fun = "cumhaz") |>
 # `fortify.survfit()` doesn't name cumhaz correctly:
 rename(cumhaz = surv) |>
 mutate(
   surv = exp(-cumhaz),
   strata = trimws(strata)) |>
 mutate(model = "Nelson-Aalen") |>
 bind_rows(stack_surv_ph(cox_model))
na_and_cph |>
 ggplot(
   aes(
     x = time,
     y = cumhaz,
     col = model)) +
 geom_step() +
 facet_wrap(~strata) +
 theme_bw() +
 scale_y_continuous(
   trans = "log10",
   name = "Cumulative hazard H(t) (log-scale)") +
 scale_x_continuous(
   trans = "log10",
   name = "Survival time (t, days, log-scale)") +
 theme(legend.position = "bottom")
```

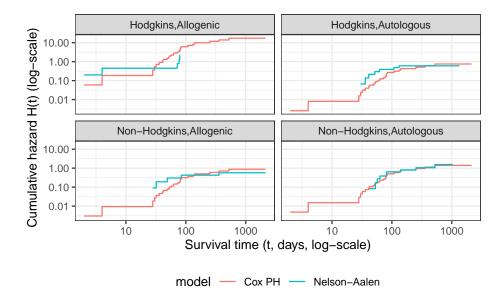

Figure 29: Observed and expected cumulative hazard curves for bmt data (cloglog format)

0.45 Predictions and Residuals

0.45.1 Review: Predictions in Linear Regression

• In linear regression, we have a linear predictor for each data point i

$$\begin{split} &\eta_i = \beta_0 + \beta_1 x_{1i} + \dots + \beta_p x_{pi} \\ &\hat{y}_i = \hat{\eta}_i = \hat{\beta}_0 + \hat{\beta}_1 x_{1i} + \dots + \hat{\beta}_p x_{pi} \\ &y_i \sim N(\eta_i, \sigma^2) \end{split}$$

• \hat{y}_i estimates the conditional mean of y_i given the covariate values \tilde{x}_i . This together with the prediction error says that we are predicting the distribution of values of y.

0.45.2 Review: Residuals in Linear Regression

- The usual residual is $r_i = y_i \hat{y}_i$, the difference between the actual value of y and a prediction of its mean.
- The residuals are also the quantities the sum of whose squares is being minimized by the least squares/MLE estimation.

0.45.3 Predictions and Residuals in survival models

- In survival analysis, the equivalent of y_i is the event time t_i , which is unknown for the censored observations.
- The expected event time can be tricky to calculate:

$$\hat{\mathbf{E}}[T|X=x] = \int_{t=0}^{\infty} \hat{S}(t) dt$$

0.45.4 Wide prediction intervals

The nature of time-to-event data results in very wide prediction intervals:

- Suppose a cancer patient is predicted to have a mean lifetime of 5 years after diagnosis and suppose the distribution is exponential.
- If we want a 95% interval for survival, the lower end is at the 0.025 percentage point of the exponential which is qexp(.025, rate = 1/5) = 0.1266 years, or 1/40 of the mean lifetime.

- The upper end is at the 0.975 point which is qexp(.975, rate = 1/5) = 18.4444 years, or 3.7 times the mean lifetime.
- Saying that the survival time is somewhere between 6 weeks and 18 years does not seem very useful, but it may be the best we can do.
- For survival analysis, something is like a residual if it is small when the model is accurate or if the accumulation of them is in some way minimized by the estimation algorithm, but there is no exact equivalence to linear regression residuals.
- And if there is, they are mostly quite large!

0.45.5 Types of Residuals in Time-to-Event Models

- It is often hard to make a decision from graph appearances, though the process can reveal much.
- Some diagnostic tests are based on residuals as with other regression methods:
- Schoenfeld residuals (via cox.zph) for proportionality.
- Cox-Snell residuals for goodness of fit.
- martingale residuals for non-linearity.
- dfbeta for influence.

0.45.6 Schoenfeld residuals

- There is a Schoenfeld residual for each subject i with an event (not censored) and for each predictor x_k .
- At the event time t for that subject, there is a risk set R, and each subject j in the risk set has a risk coefficient θ_j and also a value x_{jk} of the predictor.
- The Schoenfeld residual is the difference between x_{ik} and the risk-weighted average of all the x_{ik} over the risk set.

$$r_{ik}^S = x_{ik} - \frac{\sum_{k \in R} x_{jk} \theta_k}{\sum_{k \in R} \theta_k}$$

This residual measures how typical the individual subject is with respect to the covariate at the time of the event. Since subjects should fail more or less uniformly according to risk, the Schoenfeld residuals should be approximately level over time, not increasing or decreasing.

We can test this with the correlation with time on some scale, which could be the time itself, the log time, or the rank in the set of failure times.

The default is to use the KM curve as a transform, which is similar to the rank but deals better with censoring.

The cox.zph() function implements a score test proposed by Grambsch and Therneau⁴:

```
hodg.zph = cox.zph(hodg.cox1)
print(hodg.zph)
```

0.45.6.6 Conclusions

- From the correlation test, the Karnofsky score and the interaction with graft type disease type induce modest but statistically significant non-proportionality.
- The sample size here is relatively small (26 events in 43 subjects). If the sample size is large, very small amounts of non-proportionality can induce a significant result.
- As time goes on, autologous grafts are over-represented at their own event times, but those from HOD patients become less represented.
- Both the statistical tests and the plots are useful.

0.46 Goodness of Fit using the Cox-Snell Residuals

(references: Klein & Moeschberger textbook, §11.2, and Dobson & Barnett textbook, §10.6)

Suppose that an individual has a survival time T which has survival function S(t), meaning that $\Pr(T > t) = S(t)$. Then S(T) has a uniform distribution on (0,1).

$$\begin{split} \Pr(S(T_i) \leq u) &= \Pr(T_i > S_i^{-1}(u)) \\ &= S_i(S_i^{-1}(u)) \\ &= u \end{split}$$

Also, if U has a uniform distribution on (0,1), then what is the distribution of $-\ln(U)$?

$$\Pr(-\ln(U) < x) = \Pr(U > \exp\{-x\})$$

= 1 - e^{-x}

which is the CDF of an exponential distribution with parameter $\lambda = 1$. So,

$$r_i^{CS} \stackrel{\text{def}}{=} -\ln[\hat{S}(t_i|x_i)] = \hat{H}(t_i|\tilde{x}_i)$$

should have an exponential distribution with constant hazard $\lambda=1$ if the estimate \hat{S}_i is accurate, which means that these values should look like a censored sample from this exponential distribution. These values are called **generalized residuals** or **Cox-Snell residuals**.

```
hodg2 = hodg2 |>
mutate(cs = predict(hodg.cox1, type = "expected"))
```

```
surv.csr = survfit(
  data = hodg2,
  formula = Surv(time = cs, event = delta == "dead") ~ 1,
  type = "fleming-harrington")

autoplot(surv.csr, fun = "cumhaz") +
  geom_abline(aes(intercept = 0, slope = 1), col = "red") +
  theme_bw()
```

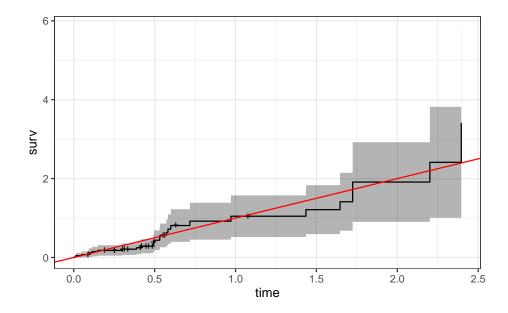

Figure 30: Cumulative Hazard of Cox-Snell Residuals

The line with slope 1 and intercept 0 fits the curve relatively well, so we don't see lack of fit using this procedure.

0.47 Martingale Residuals

The martingale residuals are a slight modification of the Cox-Snell residuals. If the censoring indicator is δ_i , then

$$r_i^M = \delta_i - r_i^{CS}$$

These residuals can be interpreted as an estimate of the excess number of events seen in the data but not predicted by the model. We will use these to examine the functional forms of continuous covariates.

0.47.1 Using Martingale Residuals

Martingale residuals can be used to examine the functional form of a numeric variable.

- We fit the model without that variable and compute the martingale residuals.
- We then plot these martingale residuals against the values of the variable.
- We can see curvature, or a possible suggestion that the variable can be discretized.

Let's use this to examine the score and wtime variables in the wtime data set.

Karnofsky score

```
hodg2 = hodg2 |>
mutate(
mres =
hodg.cox1 |>
update(. ~ . - score) |>
```

```
residuals(type="martingale"))
hodg2 |>
    ggplot(aes(x = score, y = mres)) +
    geom_point() +
    geom_smooth(method = "loess", aes(col = "loess")) +
    geom_smooth(method = 'lm', aes(col = "lm")) +
    theme_classic() +
    xlab("Karnofsky Score") +
    ylab("Martingale Residuals") +
    guides(col=guide_legend(title = ""))
```

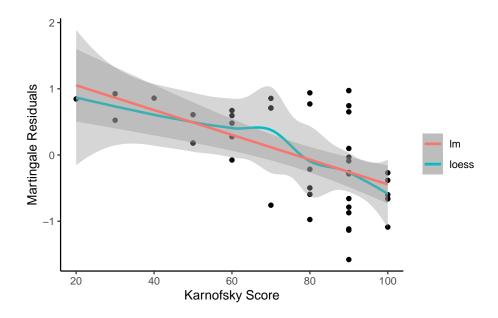

Figure 31: Martingale Residuals vs. Karnofsky Score

The line is almost straight. It could be some modest transformation of the

Karnofsky score would help, but it might not make much difference.

Waiting time

```
hodg2$mres =
hodg.cox1 |>
update(. ~ . - wtime) |>
residuals(type="martingale")

hodg2 |>
ggplot(aes(x = wtime, y = mres)) +
geom_point() +
geom_smooth(method = "loess", aes(col = "loess")) +
geom_smooth(method = 'lm', aes(col = "lm")) +
theme_classic() +
xlab("Waiting Time") +
ylab("Martingale Residuals") +
guides(col=guide_legend(title = ""))
```

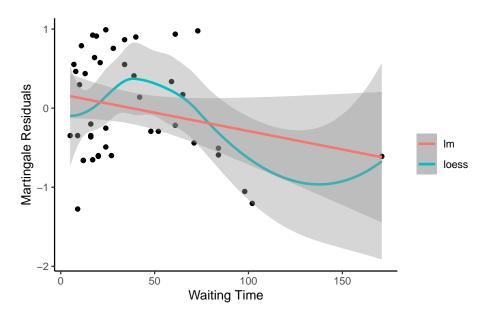

Figure 32: Martingale Residuals vs. Waiting Time

The line could suggest a step function. To see where the drop is, we can look at the largest waiting times and the associated martingale residual.

The martingale residuals are all negative for ${\tt wtime} > \!\! 83$ and positive for the next smallest value. A reasonable cut-point is 80 days.

Updating the model

Let's reformulate the model with dichotomized wtime.

```
hodg2 =
hodg2 |>
mutate(
```

```
wt2 = cut(
    wtime,c(0, 80, 200),
    labels=c("short","long")))

hodg.cox2 =
    coxph(
    formula =
        Surv(time, event = delta == "dead") ~
        gtype*dtype + score + wt2,
        data = hodg2)

hodg.cox1 |> drop1(test="Chisq")
```

Table 34: Model summary table with waiting time on continuous scale

	Df	AIC	LRT	$\Pr(>\!\!\operatorname{Chi})$
	NA	152.4	NA	NA
score	1	167.6	17.236	0.0000
wtime	1	153.6	3.279	0.0702
gtype:dtype	1	155.8	5.436	0.0197

```
hodg.cox2 |> drop1(test="Chisq")
```

Table 35: Model summary table with dichotomized waiting time

	Df	AIC	LRT	Pr(>Chi)
	NA	149.0	NA	NA
score	1	168.6	21.604	0.0000
wt2	1	153.6	6.608	0.0102
gtype:dtype	1	152.0	4.970	0.0258

The new model has better (lower) AIC.

0.48 Checking for Outliers and Influential Observations

We will check for outliers using the deviance residuals. The martingale residuals show excess events or the opposite, but highly skewed, with the maximum possible value being 1, but the smallest value can be very large negative. Martingale residuals can detect unexpectedly long-lived patients, but patients who die unexpectedly early show up only in the deviance residual. Influence will be examined using dfbeta in a similar way to linear regression, logistic regression, or Poisson regression.

0.48.1 Deviance Residuals

$$\begin{split} r_i^D &= \mathrm{sign}(r_i^M) \sqrt{-2 \left[r_i^M + \delta_i \ln(\delta_i - r_i^M)\right]} \\ r_i^D &= \mathrm{sign}(r_i^M) \sqrt{-2 \left[r_i^M + \delta_i \ln(r_i^{CS})\right]} \end{split}$$

Roughly centered on 0 with approximate standard deviation 1.

0.48.2

```
hodg.mart = residuals(hodg.cox2,type="martingale")
hodg.dev = residuals(hodg.cox2,type="deviance")
hodg.dfb = residuals(hodg.cox2,type="dfbeta")
hodg.preds = predict(hodg.cox2) #linear predictor
```

```
plot(hodg.preds,
    hodg.mart,
    xlab="Linear Predictor",
    ylab="Martingale Residual")
```

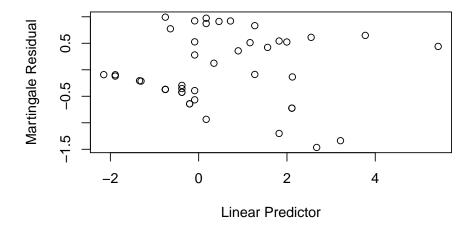

Figure 33: Martingale Residuals vs. Linear Predictor

The smallest three martingale residuals in order are observations 1, 29, and 18.

```
plot(hodg.preds,hodg.dev,xlab="Linear Predictor",ylab="Deviance Residual")
```

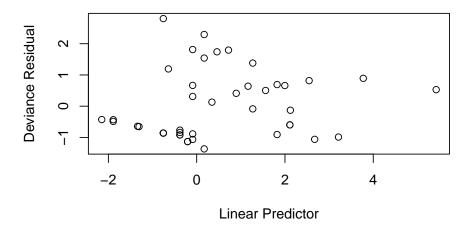

Figure 34: Deviance Residuals vs. Linear Predictor

The two largest deviance residuals are observations 1 and 29. Worth examining.

0.48.3 dfbeta

- dfbeta is the approximate change in the coefficient vector if that observation were dropped
- dfbetas is the approximate change in the coefficients, scaled by the standard error for the coefficients.

0.48.3.1 Graft type

 $\verb|plot(hodg.dfb[,1],xlab="Observation Order",ylab="dfbeta for Graft Type")| \\$

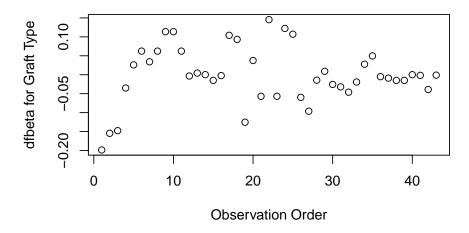

Figure 35: dfbeta Values by Observation Order for Graft Type

The smallest dfbeta for graft type is observation 1.

0.48.3.2 Disease type

```
plot(hodg.dfb[,2],
     xlab="Observation Order",
     ylab="dfbeta for Disease Type")
```

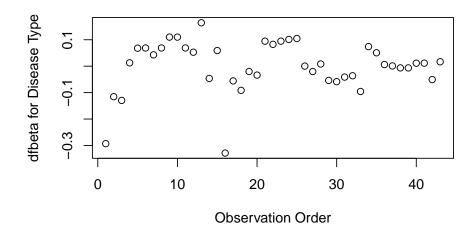

Figure 36: dfbeta Values by Observation Order for Disease Type

The smallest two dfbeta values for disease type are observations 1 and 16.

0.48.3.3 Karnofsky score

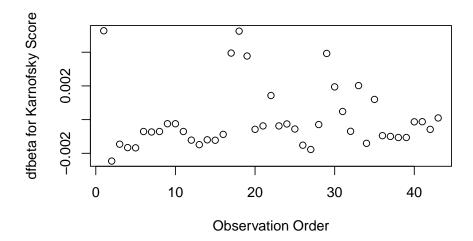

Figure 37: dfbeta Values by Observation Order for Karnofsky Score

The two highest dfbeta values for score are observations 1 and 18. The next three are observations 17, 29, and 19. The smallest value is observation 2.

0.48.3.4 Waiting time (dichotomized)

```
plot(
  hodg.dfb[,4],
  xlab="Observation Order",
  ylab="dfbeta for `Waiting Time < 80`")</pre>
```

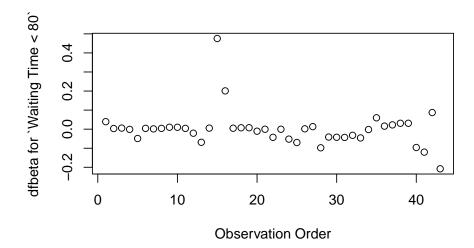

Figure 38: dfbeta Values by Observation Order for Waiting Time (dichotomized)

The two large values of dfbeta for dichotomized waiting time are observations 15 and 16. This may have to do with the discretization of waiting time.

0.48.3.5 Interaction: graft type and disease type

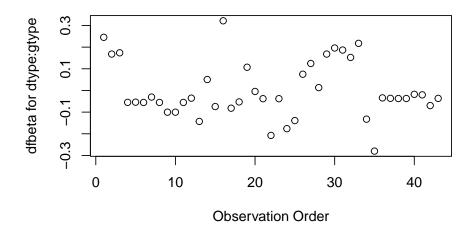

Figure 39: dfbeta Values by Observation Order for dtype:gtype

The two largest values are observations 1 and 16. The smallest value is observation 35.

0.48.4

Table 36: Observations to Examine by Residuals and Influence

Diagnostic	Observations to Examine
Martingale Residuals	1, 29, 18
Deviance Residuals	1, 29
Graft Type Influence	1
Disease Type Influence	1, 16
Karnofsky Score Influence	1, 18 (17, 29, 19)
Waiting Time Influence	15, 16
Graft by Disease Influence	1, 16, 35

The most important observations to examine seem to be $1,\,15,\,16,\,18,$ and 29.

0.48.6 Action Items

- Unusual points may need checking, particularly if the data are not completely cleaned. In this case, observations 15 and 16 may show some trouble with the dichotomization of waiting time, but it still may be useful.
- The two largest residuals seem to be due to unexpectedly early deaths, but unfortunately this can occur.
- If hazards don't look proportional, then we may need to use strata, between which the base hazards are permitted to be different. For this problem, the natural strata are the two diseases, because they could need to be managed differently anyway.
- A main point that we want to be sure of is the relative risk difference by disease type and graft type.

```
hodg.cox2 |>
predict(
    reference = "zero",
    newdata = means |>
```

```
mutate(
    wt2 = "short",
    score = 0),
    type = "lp") |>
    data.frame('linear predictor' = _) |>
    pander()
```

Table 41: Linear Risk Predictors for Lymphoma

	linear.predictor
Non-Hodgkins, Allogenic	0
Non-	0.6651
Hodgkins, Autologous	
Hodgkins, Allogenic	2.327
Hodgkins, Autologous	0.9256

For Non-Hodgkin's, the allogenic graft is better. For Hodgkin's, the autologous graft is much better.

0.49 Stratified survival models

0.49.1 Revisiting the leukemia dataset (anderson)

We will analyze remission survival times on 42 leukemia patients, half on new treatment, half on standard treatment.

This is the same data as the drug6mp data from KMsurv, but with two other variables and without the pairing. This version comes from the Kleinbaum and Klein survival textbook (e.g., p281):

```
anderson =
  paste0(
    "http://web1.sph.emory.edu/dkleinb/allDatasets/",
    "surv2datasets/anderson.dta") |>
  haven::read_dta() |>
  mutate(
    status = status |>
     case_match(
       1 ~ "relapse",
       0 ~ "censored"
      ),
    sex = sex |>
     case_match(
       0 ~ "female",
        1 ~ "male"
      ) |>
      factor() |>
      relevel(ref = "female"),
   rx = rx |>
      case_match(
       0 ~ "new",
        1 ~ "standard"
      ) |>
      factor() |> relevel(ref = "standard"),
    surv = Surv(
     time = survt,
     event = (status == "relapse"))
  )
```

print(anderson)

```
# A tibble: 42 x 7

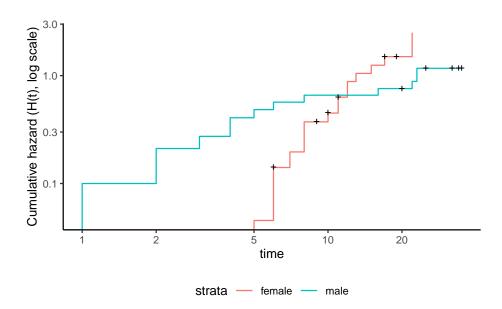

Figure 40: Cumulative hazard (cloglog scale) for anderson data

This can be fixed by using strata or possibly by other model alterations.

0.49.4 The Stratified Cox Model

- In a stratified Cox model, each stratum, defined by one or more factors, has its own base survival function $h_0(t)$.
- But the coefficients for each variable not used in the strata definitions are assumed to be the same across strata.
- To check if this assumption is reasonable one can include interactions with strata and see if they are significant (this may generate a warning and NA lines but these can be ignored).
- Since the sex variable shows possible non-proportionality, we try stratifying on sex.

Time to Event Models

loglik	Chisq	Df	Pr(> Chi)
-53.85	NA	NA	NA
-55.73	3.766	2	0.1521

We don't have enough evidence to tell the difference between these two models.

0.49.5 Conclusions

- We chose to use a stratified model because of the apparent nonproportionality of the hazard for the sex variable.
- When we fit interactions with the strata variable, we did not get an improved model (via the likelihood ratio test).
- So we use the stratifed model with coefficients that are the same across strata.

0.49.6 Another Modeling Approach

- We used an additive model without interactions and saw that we might need to stratify by sex.
- Instead, we could try to improve the model's functional form maybe the interaction of treatment and sex is real, and after fitting that we might not need separate hazard functions.
- Either approach may work.

```

This dataset comes from the Copelan et al. (1991) study of allogenic bone marrow transplant therapy for acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL).

Outcomes (endpoints)

• The main endpoint is disease-free survival (t2 and d3) for the three risk groups, "ALL", "AML Low Risk", and "AML High Risk".

Possible intermediate events

- graft vs. host disease (**GVHD**), an immunological rejection response to the transplant (bad)
- acute (AGVHD)
- chronic (CGVHD)
- platelet recovery, a return of platelet count to normal levels (good)

One or the other, both in either order, or neither may occur.

Covariates

- We are interested in possibly using the covariates z1-z10 to adjust for other factors.
- In addition, the time-varying covariates for acute GVHD, chronic GVHD, and platelet recovery may be useful.

0.50.1.1 Preprocessing

We add reformat the data before analysis:

```
# reformat the data:
bmt1 =
  bmt |>
  as_tibble() |>
 mutate(
    id = 1:n(), # will be used to connect multiple records for the same individual
    group = group |>
      case_match(
        1 ~ "ALL",
        2 ~ "Low Risk AML",
        3 ~ "High Risk AML") |>
      factor(levels = c("ALL", "Low Risk AML", "High Risk AML")),
    `patient age` = z1,
    'donor age' = z2,
    `patient sex` = z3 |>
      case_match(
        0 ~ "Female",
        1 ~ "Male"),
    donor sex = z4 >
      case_match(
        0 ~ "Female",
        1 ~ "Male"),
    `Patient CMV Status` = z5 |>
      case_match(
        0 ~ "CMV Negative",
        1 ~ "CMV Positive"),
```

```
`Donor CMV Status` = z6 |>
        case_match(
          0 ~ "CMV Negative",
          1 ~ "CMV Positive"),
      `Waiting Time to Transplant` = z7,
      FAB = z8 \mid >
        case_match(
          1 ~ "Grade 4 Or 5 (AML only)",
          0 ~ "Other") |>
        factor() |>
        relevel(ref = "Other"),
      hospital = z9 \mid >  # ^z9 is hospital
        case_match(
          1 ~ "Ohio State University",
          2 ~ "Alferd",
          3 ~ "St. Vincent",
          4 ~ "Hahnemann") |>
        factor() |>
        relevel(ref = "Ohio State University"),
      MTX = (z10 == 1) # a prophylatic treatment for GVHD
    select(-(z1:z10)) # don't need these anymore
  bmt1 |>
    select(group, id:MTX) |>
    print(n = 10)
# A tibble: 137 x 12
```

Time to Event Models

	group	id	`patient age`	`donor age`	`patient sex`	`donor sex`
	<fct></fct>	<int></int>	<int></int>	<int></int>	<chr></chr>	<chr></chr>

10	ALL	10	24	40	Male	Male

[#] i 127 more rows

0.50.2 Time-Dependent Covariates

- A time-dependent covariate ("TDC") is a covariate whose value changes during the course of the study.
- For variables like age that change in a linear manner with time, we can just use the value at the start.
- But it may be plausible that when and if GVHD occurs, the risk of relapse or death increases, and when and if platelet recovery occurs, the risk decreases.

0.50.3 Analysis in R

- We form a variable **precovery** which is = 0 before platelet recovery and is = 1 after platelet recovery, if it occurs.
- For each subject where platelet recovery occurs, we set up multiple records (lines in the data frame); for example one from t=0 to the

[#] i 6 more variables: `Patient CMV Status` <chr>, `Donor CMV Status` <chr>,

^{# `}Waiting Time to Transplant` <int>, FAB <fct>, hospital <fct>, MTX <lgl>

time of platelet recovery, and one from that time to relapse, recovery, or death.

- We do the same for acute GVHD and chronic GVHD.
- For each record, the covariates are constant.

```
bmt2 = bmt1 |>
    #set up new long-format data set:
    tmerge(bmt1, id = id, tstop = t2) |>

# the following three steps can be in any order,
# and will still produce the same result:
#add aghvd as tdc:
    tmerge(bmt1, id = id, agvhd = tdc(ta)) |>
    #add cghvd as tdc:
    tmerge(bmt1, id = id, cgvhd = tdc(tc)) |>
    #add platelet recovery as tdc:
    tmerge(bmt1, id = id, precovery = tdc(tp))

bmt2 = bmt2 |>
    as_tibble() |>
    mutate(status = as.numeric((tstop == t2) & d3))
# status only = 1 if at end of t2 and not censored
```

Let's see how we've rearranged the first row of the data:

```
bmt1 |>
  filter(id == 1) |>
  select(id, t1, d1, t2, d2, d3, ta, da, tc, dc, tp, dp)
```

id	t1	d1	t2	d2	d3	ta	da	tc	dc	tp	dp
1	2081	0	2081	0	0	67	1	121	1	13	1

The event times for this individual are:

- t = 0 time of transplant
- tp = 13 platelet recovery
- ta = 67 acute GVHD onset
- tc = 121 chronic GVHD onset
- t2 = 2081 end of study, patient not relapsed or dead

After converting the data to long-format, we have:

```
bmt2 |>
  select(
  id,
  tstart,
  tstop,
  agvhd,
  cgvhd,
  precovery,
  status
) |>
  filter(id == 1)
```

id	tstart	tstop	agvhd	cgvhd	precovery	status
1	0	13	0	0	0	0
1	13	67	0	0	1	0
1	67	121	1	0	1	0
1	121	2081	1	1	1	0

Note that status could have been 1 on the last row, indicating that relapse or death occurred; since it is false, the participant must have exited the study without experiencing relapse or death (i.e., they were censored).

0.50.4 Event sequences

Let:

- A = acute GVHD
- C = chronic GVHD
- P = platelet recovery

Each of the eight possible combinations of A or not-A, with C or not-C, with P or not-P occurs in this data set.

- A always occurs before C, and P always occurs before C, if both occur.
- Thus there are ten event sequences in the data set: None, A, C, P, AC, AP, PA, PC, APC, and PAC.
- In general, there could be as many as 1+3+(3)(2)+6=16 sequences, but our domain knowledge tells us that some are missing: CA, CP, CAP, CPA, PCA, PC, PAC
- Different subjects could have 1, 2, 3, or 4 intervals, depending on which of acute GVHD, chronic GVHD, and/or platelet recovery occurred.
- The final interval for any subject has status = 1 if the subject relapsed or died at that time; otherwise status = 0.
- Any earlier intervals have status = 0.
- Even though there might be multiple lines per ID in the dataset, there is never more than one event, so no alterations need be made in the estimation procedures or in the interpretation of the output.
- The function tmerge in the survival package eases the process of constructing the new long-format dataset.

0.50.5 Model with Time-Fixed Covariates

```

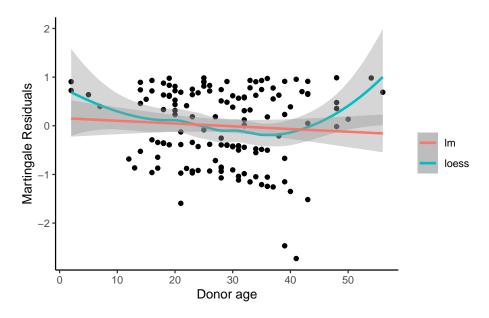

Figure 41: Martingale residuals for Donor age

A more complex functional form for donor age seems warranted; left as an exercise for the reader.

Now we will add the time-varying covariates:

```
# add counting process formulation of Surv():
bmt2 =
  bmt2 |>
  mutate(
    surv =
    Surv(
      time = tstart,
      time2 = tstop,
      event = status,
```

```

Platelet recovery is highly significant.

Neither acute GVHD (agvhd) nor chronic GVHD (cgvhd) has a statistically significant effect here, nor are they significant in models with the other one removed.

0.51 Recurrent Events

(Adapted from Kleinbaum and Klein, Ch 8)

- Sometimes an appropriate analysis requires consideration of recurrent events.
- A patient with arthritis may have more than one flareup. The same is true of many recurring-remitting diseases.
- In this case, we have more than one line in the data frame, but each line may have an event.
- We have to use a "robust" variance estimator to account for correlation of time-to-events within a patient.

0.51.1 Bladder Cancer Data Set

The bladder cancer dataset from Kleinbaum and Klein contains recurrent event outcome information for eighty-six cancer patients followed for the recurrence of bladder cancer tumor after transurethral surgical excision (Byar and Green 1980). The exposure of interest is the effect of the drug treatment of thiotepa. Control variables are the initial number and initial size of tumors. The data layout is suitable for a counting processes approach.

This drug is still a possible choice for some patients. Another therapeutic choice is Bacillus Calmette-Guerin (BCG), a live bacterium related to cow tuberculosis.

0.51.1.1 Data dictionary

Table 46: Variables in the bladder dataset

Variable	Definition
id	Patient unique ID
status	for each time interval: $1 = \text{recurred}$, $0 = \text{censored}$
interval	1 = first recurrence, etc.
intime	'tstop - tstart (all times in months)
tstart	start of interval
tstop	end of interval
tx	treatment code, $1 = \text{thiotepa}$
num	number of initial tumors
size	size of initial tumors (cm)

- There are 85 patients and 190 lines in the dataset, meaning that many patients have more than one line.
- Patient 1 with 0 observation time was removed.
- Of the 85 patients, 47 had at least one recurrence and 38 had none.
- 18 patients had exactly one recurrence.
- There were up to 4 recurrences in a patient.
- Of the 190 intervals, 112 terminated with a recurrence and 78 were censored.

0.51.1.2 Different intervals for the same patient are correlated.

- Is the effective sample size 47 or 112? This might narrow confidence intervals by as much as a factor of $\sqrt{112/47} = 1.54$
- What happens if I have 5 treatment and 5 control values and want to do a t-test and I then duplicate the 10 values as if the sample size was 20? This falsely narrows confidence intervals by a factor of $\sqrt{2} = 1.41$.

Ways to check PH assumption:

- cloglog
- schoenfeld residuals
- interaction with time

0.52 Parametric survival models

Configuring R

Functions from these packages will be used throughout this document:

```
library(pander) # format tables for markdown
library(ggplot2) # graphics
library(ggeasy) # help with graphics
library(dplyr) # manipulate data
library(haven) # import Stata files
library(knitr) # format R output for markdown
library(tidyr) # Tools to help to create tidy data
library(plotly) # interactive graphics
library(dobson) # datasets from Dobson and Barnett 2018
library(parameters) # format model output tables for markdown
library(conflicted) # check for conflicting function definitions
conflicts_prefer(dplyr::filter)
```

Here are some R settings I use in this document:

```
rm(list = ls()) # delete any data that's already loaded into R
knitr::opts_chunk$set(message = FALSE)
pander::panderOptions("table.emphasize.rownames", FALSE)
options('digits' = 4)
```

0.53 Parametric Survival Models

0.53.1 Exponential Distribution

• The exponential distribution is the basic distribution for survival analysis.

$$\begin{split} f(t) &= \lambda e^{-\lambda t} \\ \log \left\{ f(t) \right\} &= \log \left\{ \lambda \right\} - \lambda t \\ F(t) &= 1 - e^{-\lambda t} \\ S(t) &= e^{-\lambda t} \\ H(t) &= \log \left\{ S(t) \right\} = -\lambda t \\ h(t) &= \lambda \\ \mathrm{E}(T) &= \lambda^{-1} \end{split}$$

0.53.2 Weibull Distribution

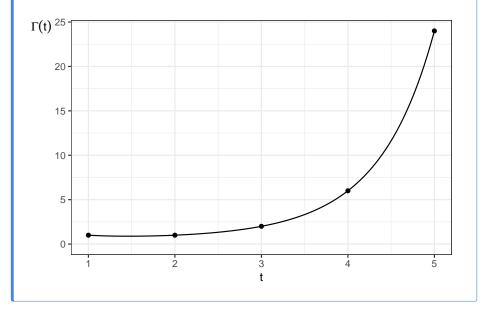

Using the Kalbfleisch and Prentice (2002) notation:

$$\begin{split} f(t) &= \lambda p (\lambda t)^{p-1} e^{-(\lambda t)^p} \\ F(t) &= 1 - e^{-(\lambda t)^p} \\ S(t) &= e^{-(\lambda t)^p} \\ h(t) &= \lambda p (\lambda t)^{p-1} \\ H(t) &= (\lambda t)^p \\ \log \left\{ H(t) \right\} &= p \log \left\{ \lambda t \right\} = p \log \left\{ \lambda \right\} + p \log \left\{ t \right\} \\ \mathrm{E}(T) &= \lambda^{-1} \cdot \Gamma \left(1 + \frac{1}{p} \right) \end{split}$$

Note

Recall from calculus:

- $\Gamma(t) \stackrel{\text{def}}{=} \int_{u=0}^{\infty} u^{t-1} e^{-u} du$
- $\Gamma(t) = (t-1)!$ for integers $t \in \mathbb{Z}$
- It is implemented by the gamma() function in R.

Here are some Weibull density functions, with $\lambda=1$ and p varying:

```
library(ggplot2)
lambda = 1
ggplot() +
  geom_function(
```

```
aes(col = "0.25"),
  fun = \(x) dweibull(x, shape = 0.25, scale = 1/lambda)) +
geom_function(
  aes(col = "0.5"),
  fun = \(x) dweibull(x, shape = 0.5, scale = 1/lambda)) +
geom_function(
  aes(col = "1"),
  fun = \(x) dweibull(x, shape = 1, scale = 1/lambda)) +
geom_function(
  aes(col = "1.5"),
  fun = \(x) dweibull(x, shape = 1.5, scale = 1/lambda)) +

  aes(col = "2"),
  fun = \(x) dweibull(x, shape = 2, scale = 1/lambda)) +
geom_function(
  aes(col = "5"),
  fun = \(x) dweibull(x, shape = 5, scale = 1/lambda)) +
theme_bw() +
xlim(0, 2.5) +
ylab("f(t)") +
theme(axis.title.y = element_text(angle=0)) +
theme(legend.position="bottom") +
guides(
  col =
    guide_legend(
      title = "p",
      label.theme =
        element_text(
          size = 12)))
```

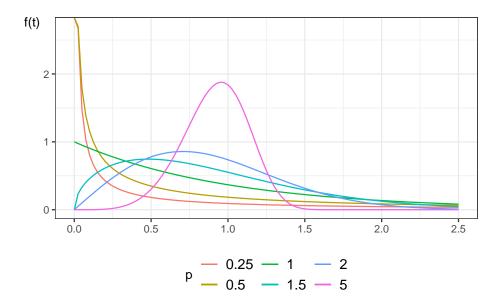

Figure 42: Density functions for Weibull distribution

0.53.2.1 Properties of Weibull hazard functions

- When p=1, the Weibull distribution simplifies to the exponential distribution
- When p > 1, the hazard is increasing
- When p < 1, the hazard is decreasing

In HW: prove these properties

This distribution provides more flexibility than the exponential.

Here are some Weibull hazard functions, with $\lambda = 1$ and p varying:

```
library(ggplot2)
library(eha)
lambda = 1
ggplot() +
  geom_function(
    aes(col = "0.25"),
    fun = \(x) hweibull(x, shape = 0.25, scale = 1/lambda)) +
  geom_function(
    aes(col = "0.5"),
    fun = \(x) hweibull(x, shape = 0.5, scale = 1/lambda)) +
  geom_function(
    aes(col = "1"),
    fun = \(x) hweibull(x, shape = 1, scale = 1/lambda)) +
  geom_function(
    aes(col = "1.5"),
    fun = \(x) hweibull(x, shape = 1.5, scale = 1/lambda)) +
  geom_function(
    aes(col = "2"),
    fun = (x) hweibull(x, shape = 2, scale = 1/lambda)) +
  theme_bw() +
  xlim(0, 2.5) +
  ylab("h(t)") +
  theme(axis.title.y = element_text(angle=0)) +
  theme(legend.position="bottom") +
  guides(
    col =
      guide_legend(
        title = "p",
        label.theme =
          element_text(
            size = 12)))
```

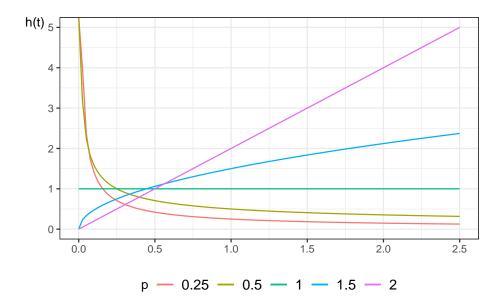

Figure 43: Hazard functions for Weibull distribution

```
library(ggplot2)
lambda = 1

ggplot() +
    geom_function(
    aes(col = "0.25"),
    fun = \(x) pweibull(lower = FALSE, x, shape = 0.25, scale = 1/lambda)) +

theme(axis.title.y = element_text(angle=0)) +
theme(legend.position="bottom") +
guides(
 col =
    guide_legend(
     title = "p",
      label.theme =
        element_text(
          size = 12)))
```

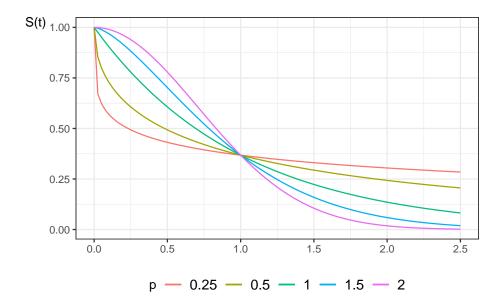

Figure 44: Survival functions for Weibull distribution

0.53.3 Exponential Regression

For each subject i, define a linear predictor:

$$\begin{split} \eta(x) &= \beta_0 + (\beta_1 x_1 + \dots + \beta_p x_p) \\ h(t|x) &= \exp \left\{ \eta(x) \right\} \\ h_0 &\stackrel{\text{def}}{=} h(t|0) \\ &= \exp \left\{ \eta(0) \right\} \\ &= \exp \left\{ \beta_0 + (\beta_1 \cdot 0 + \dots + \beta_p \cdot 0) \right\} \\ &= \exp \left\{ \beta_0 + 0 \right\} \\ &= \exp \left\{ \beta_0 \right\} \end{split}$$

We let the linear predictor have a constant term, and when there are no additional predictors the hazard is $\lambda = \exp{\{\beta_0\}}$. This has a log link as in a generalized linear model. Since the hazard does not depend on t, the hazards are (trivially) proportional.

0.53.4 Accelerated Failure Time

Previously, we assumed the hazards were proportional; that is, the covariates multiplied the baseline hazard function:

$$\begin{split} h(T=t|X=x) &\stackrel{\text{def}}{=} p(T=t|X=x, T \geq t) \\ &= h(t|X=0) \cdot \exp\left\{\eta(x)\right\} \\ &= h(t|X=0) \cdot \theta(x) \\ &= h_0(t) \cdot \theta(x) \end{split}$$

and correspondingly,

$$\begin{split} H(t|x) &= \theta(x) H_0(t) \\ S(t|x) &= \exp\left\{-H(t|x)\right\} \\ &= \exp\left\{-\theta(x) \cdot H_0(t)\right\} \\ &= \left(\exp\left\{-H_0(t)\right\}\right)^{\theta(x)} \\ &= \left(S_0(t)\right)^{\theta(x)} \end{split}$$

An alternative modeling assumption would be

$$S(t|X=x) = S_0(t \cdot \theta(x))$$

where $\theta(x)=\exp\{\eta(x)\}$, $\eta(x)=\beta_1x_1+\cdots+\beta_px_p$, and $S_0(t)=P(T\geq t|X=0)$ is the base survival function.

Then

$$\begin{split} E(T|X=x) &= \int_{t=0}^{\infty} S(t|x) dt \\ &= \int_{t=0}^{\infty} S_0(t \cdot \theta(x)) dt \\ &= \int_{u=0}^{\infty} S_0(u) du \cdot \theta(x)^{-1} \\ &= \theta(x)^{-1} \cdot \int_{u=0}^{\infty} S_0(u) du \\ &= \theta(x)^{-1} \cdot \mathrm{E}(T|X=0) \end{split}$$

So the mean of T given X=x is the baseline mean divided by $\theta(x)=\exp{\{\eta(x)\}}.$

This modeling strategy is called an accelerated failure time model, because covariates cause uniform acceleration (or slowing) of failure times.

Additionally:

$$\begin{split} H(t|x) &= H_0(\theta(x) \cdot t) \\ h(t|x) &= \theta(x) \cdot h_0(\theta(x) \cdot t) \end{split}$$

If the base distribution is exponential with parameter λ then

$$\begin{split} S(t|x) &= \exp\left\{-\lambda \cdot t\theta(x)\right\} \\ &= \left[\exp\left\{-\lambda t\right\}\right]^{\theta(x)} \end{split}$$

which is an exponential model with base hazard multiplied by $\theta(x)$, which is also the proportional hazards model.

In terms of the log survival time $Y = \log \{T\}$ the model can be written as

$$Y = \alpha - \eta + W$$
$$\alpha = -\log \{\lambda\}$$

where W has the extreme value distribution. The estimated parameter λ is the intercept and the other coefficients are those of η , which will be the opposite sign of those for coxph.

For a Weibull distribution, the hazard function and the survival function are

$$h(t) = \lambda p(\lambda t)^{p-1}$$

$$S(t) = e^{-(\lambda t)^p}$$

We can construct a proportional hazards model by using a linear predictor η_i without constant term and letting $\theta_i = e^{\eta_i}$ we have

$$h(t) = \lambda p(\lambda t)^{p-1} \theta_i$$

A distribution with $h(t)=\lambda p(\lambda t)^{p-1}\theta_i$ is a Weibull distribution with parameters $\lambda^*=\lambda\theta_i^{1/p}$ and p so the survival function is

$$S^*(t) = e^{-(\lambda^* t)^p}$$

$$= e^{-(\lambda \theta^{1/p} t)^p}$$

$$= S(t\theta^{1/p})$$

so this is also an accelerated failure time model.

In terms of the log survival time $Y = \log\{T\}$ the model can be written as

$$Y = \alpha - \sigma \eta + \sigma W$$
$$\alpha = -\log \{\lambda\}$$
$$\sigma = 1/p$$

where W has the extreme value distribution. The estimated parameter λ is the intercept and the other coefficients are those of η , which will be the opposite sign of those for coxph.

These AFT models are log-linear, meaning that the linear predictor has a log link. The exponential and the Weibull are the only log-linear models that are simultaneously proportional hazards models. Other parametric distributions can be used for survival regression either as a proportional hazards model or as an accelerated failure time model.

0.53.5 Dataset: Leukemia treatments

Remission survival times on 42 leukemia patients, half on new treatment, half on standard treatment.

This is the same data as the drug6mp data from KMsurv, but with two other variables and without the pairing.

0.54 Introduction to Maximum Likelihood Inference

These notes are derived primarily from:

Dobson, Annette J., and Adrian G. Barnett. An introduction to generalized linear models. 3rd edition. CRC press, 2008 (mostly chapters 3-5).

I've added this book to the "Reading List" on canvas, so it should be uploaded there by the librarians soon.

Some material was also taken from:

McLachlan, Geoffrey J., and Thriyambakam Krishnan. The EM algorithm and extensions. John Wiley & Sons, 2007. https://onlinelibrary.wiley.com/doi/book/10.1002/9780470191613

Casella, G., & Berger, R. L. (2002). Statistical inference. 2nd ed. Australia; Pacific Grove, CA, Thomson Learning.

0.55 Maximum likelihood inference for univariate Gaussian models

Suppose $X_1,\dots,X_n\sim_{iid} N\left(\mu,\ \sigma^2\right)$. Let $X=\left(X_1,\dots,X_n\right)^{\top}$ be these random variables in vector format. Let x_i and x denote the corresponding observed data. Let $\theta=\left(\mu,\sigma^2\right)^{\top}$ be the vector of parameters. Let Θ denote the parameters as a random vector.

Then the log-likelihood $\ell \stackrel{\text{def}}{=} \ell(X; \theta) \stackrel{\text{def}}{=} p\left(X = x \mid \Theta = \theta\right)$ is:

$$\begin{split} \ell & \propto -\frac{n}{2} \mathrm{log} \left\{ \sigma^2 \right\} - \frac{1}{2} \sum_{i=1}^{n} \frac{\left(x_i - \mu \right)^2}{\sigma^2} \\ & = -\frac{n}{2} \mathrm{log} \left\{ \sigma^2 \right\} - \frac{1}{2\sigma^2} \sum_{i=1}^{n} x_i^2 - 2 x_i \mu + \mu^2 \end{split}$$

0.55.1 MLE of μ :

Then:

$$\frac{d\ell}{d\mu} = -\frac{1}{2} \sum_{i=1}^{n} \frac{-2\left(x_{i} - \mu\right)}{\sigma^{2}}$$

$$=\frac{1}{\sigma^2}\left[\left(\sum_{i=1}^n x_i\right)-n\mu\right]$$

If $\frac{d\ell}{d\mu} = 0$, then $\mu = \overline{x} \stackrel{\text{def}}{=} \frac{1}{n} \sum_{i=1}^{n} x_i$.

$$\frac{d^2\ell}{(d\mu)^2} = \frac{-n}{\sigma^2} < 0$$

So $\hat{\mu}_{ML} = \overline{x}$.

0.55.2 MLE of σ^2

? Reparametrizing the Gaussian distribution

When solving for $\hat{\sigma}_{ML}$, you can treat σ^2 as an atomic variable (don't differentiate with respect to σ or things get messy). In fact, you can replace σ^2 with $1/\tau$ and differentiate with respect to τ instead, and the process might be even easier.

$$\begin{split} \frac{d\ell}{d\sigma^2} &= \frac{d}{d\sigma^2} \left(-\frac{n}{2} \mathrm{log} \left\{ \sigma^2 \right\} - \frac{1}{2} \sum_{i=1}^n \frac{\left(x_i - \mu \right)^2}{\sigma^2} \right) \\ &= -\frac{n}{2} \left(\sigma^2 \right)^{-1} + \frac{1}{2} \left(\sigma^2 \right)^{-2} \sum_{i=1}^n \left(x_i - \mu \right)^2 \end{split}$$

If $\frac{d\ell}{d\sigma^2} = 0$, then:

$$\frac{n}{2} (\sigma^2)^{-1} = \frac{1}{2} (\sigma^2)^{-2} \sum_{i=1}^{n} (x_i - \mu)^2$$
$$\sigma^2 = \frac{1}{n} \sum_{i=1}^{n} (x_i - \mu)^2$$

We plug in $\hat{\mu}_{ML}=\overline{x}$ to maximize globally (a technique called profiling):

$$\sigma_{ML}^2 = \frac{1}{n} \sum_{i=1}^n \left(x_i - \overline{x} \right)^2$$

Now:

$$\begin{split} \frac{d^2\ell}{\left(d\sigma^2\right)^2} &= \frac{d}{d\sigma^2} \left\{ -\frac{n}{2} \left(\sigma^2\right)^{-1} + \frac{1}{2} \left(\sigma^2\right)^{-2} \sum_{i=1}^n \left(x_i - \mu\right)^2 \right\} \\ &= \left\{ -\frac{n}{2} \frac{d}{d\sigma^2} \left(\sigma^2\right)^{-1} + \frac{1}{2} \frac{d}{d\sigma^2} \left(\sigma^2\right)^{-2} \sum_{i=1}^n \left(x_i - \mu\right)^2 \right\} \\ &= \left\{ \frac{n}{2} \left(\sigma^2\right)^{-2} - \left(\sigma^2\right)^{-3} \sum_{i=1}^n \left(x_i - \mu\right)^2 \right\} \\ &= \left(\sigma^2\right)^{-2} \left\{ \frac{n}{2} - \left(\sigma^2\right)^{-1} \sum_{i=1}^n \left(x_i - \mu\right)^2 \right\} \end{split}$$

Evaluated at $\mu = \overline{x}, \sigma^2 = \frac{1}{n} \sum_{i=1}^n \left(x_i - \overline{x}\right)^2$, we have:

$$\begin{split} \frac{d^2\ell}{\left(d\sigma^2\right)^2} &= \left(\hat{\sigma}^2\right)^{-2} \left\{ \frac{n}{2} - \left(\hat{\sigma}^2\right)^{-1} \sum_{i=1}^n \left(x_i - \overline{x}\right)^2 \right\} \\ &= \left(\hat{\sigma}^2\right)^{-2} \left\{ \frac{n}{2} - \left(\hat{\sigma}^2\right)^{-1} n \hat{\sigma}^2 \right\} \\ &= \left(\hat{\sigma}^2\right)^{-2} \left\{ \frac{n}{2} - n \right\} \\ &= \left(\hat{\sigma}^2\right)^{-2} n \left\{ \frac{1}{2} - 1 \right\} \\ &= \left(\hat{\sigma}^2\right)^{-2} n \left(-\frac{1}{2} \right) < 0 \end{split}$$

Finally, we have:

$$\begin{split} \frac{d^2\ell}{d\mu\;d\sigma^2} &= \frac{d}{d\mu} \left\{ -\frac{n}{2} \left(\sigma^2\right)^{-1} + \frac{1}{2} \left(\sigma^2\right)^{-2} \sum_{i=1}^n \left(x_i - \mu\right)^2 \right\} \\ &= \frac{1}{2} \left(\sigma^2\right)^{-2} \frac{d}{d\mu} \sum_{i=1}^n \left(x_i - \mu\right)^2 \\ &= \frac{1}{2} \left(\sigma^2\right)^{-2} \sum_{i=1}^n -2(x_i - \mu) \\ &= -\left(\sigma^2\right)^{-2} \sum_{i=1}^n \left(x_i - \mu\right) \end{split}$$

Evaluated at $\mu = \hat{\mu} = \overline{x}, \sigma^2 = \hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \left(x_i - \overline{x}\right)^2$, we have:

$$\frac{d^2\ell}{d\mu\;d\sigma^2} = -\left(\widehat{\sigma}^2\right)^{-2}(n\overline{x}-n\overline{x}) = 0$$

0.55.3 Covariance matrix of MLEs

0.55.3.1 The score function

Let θ be the vector of all parameters; here, $\theta = (\mu, \sigma^2)^{\top}$.

Let
$$\ell'(x,\theta) \stackrel{\text{def}}{=} \frac{d}{d\theta} \ell(x,\theta) = \begin{pmatrix} \frac{d}{d\mu} \ell(\theta;x) \\ \frac{d}{d\sigma^2} \ell(\theta;x) \end{pmatrix} = \begin{pmatrix} \ell'_{\mu}(\theta;x) \\ \ell'_{\sigma^2}(\theta;x) \end{pmatrix}$$
.

 $\ell^{'}(x,\theta)$ is the function we set equal to 0 and solve to find the MLE:

$$\hat{\theta}_{ML} = \left\{ \theta : \ell'(x, \theta) = 0 \right\}$$

The function $\ell'(x,\theta)$ is so central that it has its own name, the "score" or "gradient" function. Statisticians also often skip writing the arguments (x,θ) , so $\ell' \stackrel{\text{def}}{=} \ell'(x,\theta)$. Some statisticians use U or S instead of ℓ' . I prefer ℓ' . Why use up extra letters?

0.55.3.2 The (Fisher) (expected) information matrix

The variance of $\ell'(x,\theta)$, $Cov\left\{\ell'(x,\theta)\right\}$, is also very important; we call it the "expected information matrix", "Fisher information matrix", or just "information matrix", and we represent it using the symbol \Im (\frakturI in Unicode, \mathfrak{I} in LaTeX).

Review of variances and covariances

⁵I might sometimes switch the order of x, θ ; this is unintentional and not meaningful.

Variances and covariances of one-dimensional random variables

For a one-dimensional random variables X,

$$Var(X) \stackrel{\mathrm{def}}{=} \mathrm{E} \left[\left(X - \mathrm{E}[X] \right)^2 \right] = \mathrm{E} \left[X^2 \right] - \left(\mathrm{E}[X] \right)^2$$

For any two-dimensional random variables, X, Y:

$$Cov(X,Y) = E\left[(X - \mathrm{E}X)(Y - \mathrm{E}Y)\right] = \mathrm{E}[XY] - E[X]E[Y]$$

Therefore, $Var(X) = Cov(X, X) = E[XX] - E[X]E[X] = E[X^2] - (E[X])^2$

$$\mathfrak{I} \stackrel{\mathrm{def}}{=} \mathfrak{I}(\boldsymbol{\theta}) \stackrel{\mathrm{def}}{=} Cov\left(\boldsymbol{\ell}'|\boldsymbol{\theta}\right) = \mathbf{E}\left[\boldsymbol{\ell}'\boldsymbol{\ell'}^{\top}\right] - \mathbf{E}\left[\boldsymbol{\ell}'\right] \ \mathbf{E}\left[\boldsymbol{\ell}'\right]^{\top}$$

Sometimes we write $Cov(X) \stackrel{\text{def}}{=} Cov(X, X) = Var(X)$.

Variances and covariances of $p \times 1$ random vectors

Now, for a $p \times 1$ dimensional random vector X,

$$\begin{aligned} \operatorname{Var}(X) &\stackrel{\text{def}}{=} \operatorname{Cov}(X) \\ &\stackrel{\text{def}}{=} E\left[(X - E[X])^{\top} \left(X - E[X] \right) \right] \\ &= E\left[(X^{\top} - E[X]^{\top}) \left(X - E[X] \right) \right] \\ &= E\left[X^{\top} X - E[X]^{\top} X - X^{\top} E[X] + E[X]^{\top} E[X] \right] \\ &= E\left[X^{\top} X \right] - E[X]^{\top} E[X] - E[X]^{\top} E[X] + E[X]^{\top} E[X] \\ &= E\left[X^{\top} X \right] - 2 E[X]^{\top} E[X] + E[X]^{\top} E[X] \\ &= E\left[X^{\top} X \right] - E[X]^{\top} E[X] \end{aligned}$$

The elements of \Im are:

$$\left\{ \Im_{ij} \stackrel{\mathrm{def}}{=} Cov\left(\ell^{'}{}_{i},\ell^{'}{}_{j}\right) = \mathrm{E}\left[\ell^{'}_{i}\ell^{'}_{j}\right] - \mathrm{E}\left[\ell^{'}{}_{i}\right] \mathrm{E}\left[\ell^{'}{}_{j}\right] \right\}$$

In our motivating example, $i, j \in \{\mu, \sigma^2\}$. Here,

$$E[\ell'] \stackrel{\text{def}}{=} \int_{x \in \mathcal{R}(x)} \ell'(x, \theta) p(X = x | \theta) dx$$

$$= \int_{x \in \mathcal{R}(x)} \left(\frac{d}{d\theta} \log \left\{ p \left(X = x \mid \theta \right) \right\} \right) p \left(X = x \mid \theta \right) dx$$

$$= \int_{x \in \mathcal{R}(x)} \frac{\frac{d}{d\theta} p \left(X = x \mid \theta \right)}{p \left(X = x \mid \theta \right)} p \left(X = x \mid \theta \right) dx$$

$$= \int_{x \in \mathcal{R}(x)} \frac{d}{d\theta} p \left(X = x \mid \theta \right) dx$$

And similarly

$$\mathrm{E}\left[\boldsymbol{\ell}'\boldsymbol{\ell'}^{\top}\right] \stackrel{\mathrm{def}}{=} \int_{x \in R(x)} \boldsymbol{\ell}'(x,\theta)\boldsymbol{\ell}'(x,\theta)^{\top} \ p\left(X = x \mid \theta\right) \ dx$$

Note that $\mathbf{E}\left[\ell'\right]$ and $\mathbf{E}\left[\ell'\ell'^{\top}\right]$ are functions of θ but not of x; the expectation operator removed x.

Also note that for most of the distributions you are familiar with (including Gaussian, binomial, Poisson, exponential),

$$\mathbf{E}\left[\boldsymbol{\ell}'\right]=0$$

So

$$\mathfrak{I} = \mathrm{E} \left[\boldsymbol{\ell}' {\boldsymbol{\ell}'}^\top \right]$$

Moreover, for those distributions (called the "exponential family"), we have:

$$\mathfrak{I} = -\mathbf{E}\left[\ell''\right] = \mathbf{E}\left[-\ell''\right]$$

(see Dobson and Barnett 4e, §3.17), where

$$\boldsymbol{\ell}'' \stackrel{\text{def}}{=} \frac{d}{d\theta} \boldsymbol{\ell}'^{(x,\theta)^\top} = \frac{d}{d\theta} \frac{d}{d\theta^\top} \boldsymbol{\ell}(x,\theta)$$

is the $p \times p$ matrix whose elements are:

$$\ell_{ij}^{"} \stackrel{\text{def}}{=} \frac{d}{d\theta_i} \frac{d}{d\theta_j} \log \left\{ p \left(X = x \mid \theta \right) \right\}$$

 $\ell^{''}$ could be called the "Hessian" of the log-likelihood function.

Sometimes, we use $I(\theta;x) \stackrel{\text{def}}{=} -\ell''$ (note the standard-font "I" here). $I(\theta;x)$ is the observed information matrix (Negative Hessian).

Key point

The asymptotics of MLEs gives us $\hat{\theta}_{ML}\sim N\left(\theta,\Im^{-1}(\theta)\right)$, approximately, for large sample sizes.

We can estimate $\mathfrak{I}^{-1}(\theta)$ by working out $-\mathbb{E}\left[\ell''\right]$ or $\mathbb{E}\left[\ell'\ell'^{\top}\right]$ and plugging in $\hat{\theta}_{ML}$, but sometimes we instead use $I\left(\hat{\theta}_{ML};x\right)$ for convenience; there are some cases where it's provably better according to some criteria (Efron & Hinkley 1978).

Note that later, when we are trying to find MLEs for likelihoods that we can't easily differentiate, we will "hill-climb" using the Newton-Raphson algorithm:

$$\begin{split} \hat{\theta} &\leftarrow \hat{\theta} + \left[I \left(\hat{\theta}, y \right) \right]^{-1} \ell' \left(y, \hat{\theta} \right) \\ &= \hat{\theta} - \left[\ell'' \left(y, \hat{\theta} \right) \right]^{-1} \ell' \left(y, \hat{\theta} \right) \end{split}$$

Here, for computational simplicity, we will sometimes use $\mathfrak{I}^{-1}(\theta)$ in place of $I\left(\hat{\theta},y\right)$; doing so is called "Fisher scoring" or the "method of scoring". Note that this is the opposite of the substitution that we are making for estimating the variance of the MLE; this time we should technically use the observed information but we use the expected information instead.

There's also an "empirical information matrix" (see McLachlan and Krishnan 2007).

$$I_e(\theta,y) = \sum_{i=1}^n \ell_i^{'} \; {\ell_i^{'}}^{\top} - \frac{1}{n} {\ell^{'}} {\ell^{'}}^{\top}$$

where ℓ_i is the log-likelihood of the ith observation. Note that $\ell' = \sum_{i=1}^n \ell_i'$.

 $\frac{1}{n}I_e(\theta,y)$ is the sample equivalent of

$$\mathfrak{I} \stackrel{\mathrm{def}}{=} \mathfrak{I}(\theta) \stackrel{\mathrm{def}}{=} Cov\left(\boldsymbol{\ell}'|\boldsymbol{\theta}\right) = \mathbf{E}\left[\boldsymbol{\ell}'\boldsymbol{\ell}'^{\top}\right] - \mathbf{E}\left[\boldsymbol{\ell}'\right] \ \mathbf{E}\left[\boldsymbol{\ell}'\right]^{\top}$$

$$\left\{ {{\Im _{jk}}\mathop = \limits^{\mathop{\rm def}} {Cov\left({{{\boldsymbol{\ell}'}_j},{{\boldsymbol{\ell}'}_k}} \right)} = {\rm{E}}\left[{{{\boldsymbol{\ell}'_j}{\boldsymbol{\ell}'_k}}} \right] - {\rm{E}}\left[{{{\boldsymbol{\ell}'}_j}} \right]{\rm{E}}\left[{{{\boldsymbol{\ell}'}_k}} \right] \right\}$$

 $I_e(\theta, y)$ is sometimes computationally easier to compute for Newton-Raphson-type maximization algorithms.

Back to our Gaussian example:

$$I = \begin{bmatrix} \frac{n}{\sigma^2} & 0\\ 0 & (\hat{\sigma}^2)^{-2} n\left(-\frac{1}{2}\right) \end{bmatrix} = \begin{bmatrix} a & 0\\ 0 & d \end{bmatrix}$$

So:

$$I^{-1} = \frac{1}{ad} \begin{bmatrix} d & 0 \\ 0 & a \end{bmatrix} = \begin{bmatrix} \frac{1}{a} & 0 \\ 0 & \frac{1}{d} \end{bmatrix}$$

$$I^{-1} = \begin{bmatrix} \frac{\widehat{\sigma}^2}{n} & 0\\ 0 & \frac{2(\widehat{\sigma}^2)^2}{n} \end{bmatrix}$$

See Casella-Berger p322, example 7.2.12.

To prove it's a maximum, need:

- $\ell' = 0$
- At least one diagonal element of l'' is negative.
- Determinant of l'' is positive.

0.55.4 Confidence intervals for MLEs

0.55.5 p-values and hypothesis tests for MLEs

0.55.6 Likelihood ratio tests for MLEs

[We haven't gone over this yet]

Log-likelihood ratio tests (Dobson & Barnett 5.7)

$$2(l-\ell_0) \sim \chi^2(p-q)$$

0.55.7 Prediction intervals for MLEs

$$\overline{X} \in \left[\hat{\mu} \pm z_{1-\alpha/2} \frac{\sigma}{m} \right]$$

Where m is the sample size of the new data to be predicted (typically 1, except for binary outcomes, where it needs to be bigger for prediction intervals to make sense)

0.56 Estimation

0.57 Definitions

0.57.1 Bias

The **bias** of an estimator $\hat{\theta}$ for an estimand θ is the signed difference between the expected value (mean) of that estimator minus the true value of the estimand; that is:

$$\operatorname{Bias}\left(\hat{\theta}\right) \stackrel{\text{def}}{=} \operatorname{E}\left[\hat{\theta}\right] - \theta$$

0.57.2 Precision

The **precision** of an estimator $\hat{\theta}$, often denoted $\tau(\hat{\theta})$, is the inverse of that estimator's variance; that is:

$$\tau(\hat{\theta}) \stackrel{\text{def}}{=} \left(\operatorname{Var} \left(\hat{\theta} \right) \right)^{-1}$$
